# DECLARATION

I, **Chimalamarry Naga Shivani Sharma**, a student pursuing **Master of Business Administration- Data Science** and **Semester-IV** at **Amity University Online**, hereby declare that the project work entitled "**DocSnap: Intelligent Summarization for Fast Decision-Making**" has been prepared by me during the **academic year 2026** under the guidance of **Kunwar Saurabh Bisen**. I assert that this project is a piece of original bona-fide work done by me. It is the outcome of my own effort and that it has not been submitted to any other university for the award of any degree.

**Chimalamarry Naga Shivani Sharma**

*Signature of Student*

## ABSTRACT

DocSnap is an intelligent document summarization system designed to address the growing challenge of information overload in modern professional and organizational environments. The project leverages state-of-the-art transformer-based natural language processing (NLP) models — specifically T5-small, T5-base, and BERT — alongside the classical TextRank graph-based algorithm to automatically generate concise, coherent, and factually grounded summaries from long-form textual content. The system was developed, trained, evaluated, and deployed as part of an industry internship at Keystone Advisory Group, Chennai, Tamil Nadu, under the MBA (Data Science) program at Amity University Online during Academic Year 2026. The complete project lifecycle — from data acquisition and exploratory analysis through model fine-tuning, quantitative evaluation, API development, and public cloud deployment — was executed within a five-week sprint-based development cycle, demonstrating that production-grade NLP systems can be built and deployed in resource-constrained academic and organizational settings.

The primary motivation for this project stems from the exponential growth of unstructured textual data in organizational settings, which creates a critical bottleneck in knowledge work where the capacity to read, comprehend, and synthesize large bodies of text limits the speed and quality of decision-making. Professionals in corporate, legal, medical, financial, and advisory domains routinely encounter documents exceeding thousands of words — annual reports, regulatory filings, research publications, policy documents, and market analyses — that must be reviewed under tight time constraints. Automatic text summarization offers a technologically mature and practically deployable solution to this challenge: by algorithmically condensing a document while preserving its essential information, summarization tools can dramatically reduce the time investment

required for document review without sacrificing informational completeness. DocSnap was designed specifically to provide this capability in a form accessible to non-technical users through an intuitive web interface and a developer-friendly REST API.

This research employed two primary datasets: the CNN/DailyMail corpus — one of the most widely used benchmark datasets in text summarization research — comprising 287,113 training articles, 13,368 validation samples, and 11,490 test samples, with an average article length of 615 words and average reference summary length of 44 words; and a curated collection of 2,000 ArXiv research papers from the cs.CL and cs.AI subject areas representing the scientific domain. These two datasets were deliberately chosen to represent different text genres (journalistic vs. scientific) and to enable cross-domain analysis of summarization challenges. Exploratory data analysis (EDA) of these corpora revealed 67,659 unique vocabulary tokens in the CNN/DailyMail dataset, with a total of 1,724,383 tokens analyzed across the training split. Named entity recognition (NER) identified 11,622 entity mentions across 500 sampled articles, with GPE (geopolitical entities) being the most prevalent entity type at 2,466 occurrences, followed by PERSON and ORGANIZATION entities. The average compression ratio of 14x in the CNN/DailyMail dataset underscores the high degree of condensation required — reference summaries capture the article content in approximately 7% of the original word count.

Four summarization models were implemented and rigorously compared across two paradigms. In the extractive paradigm: TextRank, a graph-based sentence ranking algorithm based on PageRank principles, and BERT (fine-tuned), a transformer-based sentence classifier that leverages bidirectional contextual representations to identify the most summary-worthy sentences. In the abstractive paradigm: T5-small (60M parameters, fine-tuned) and T5-base (220M parameters, fine-tuned), both using the Text-to-Text Transfer Transformer architecture with the task prefix

"summarize:" to condition the model on the summarization objective. All models were trained on Google Colab using a T4 GPU with 16GB VRAM. BERT fine-tuning achieved a validation classification accuracy of 87.5% after three training epochs with a final loss of 0.2958. T5-small training demonstrated stable convergence, reducing sequence generation loss from 2.2887 (Epoch 1) to 2.1333 (Epoch 2) to 2.0576 (Epoch 3). T5-base showed superior convergence, reducing loss from 1.7193 (Epoch 1) to 1.4822 (Epoch 2) to 1.3320 (Epoch 3), confirming the greater representational capacity of the larger model.

The final quantitative evaluation was conducted on a held-out test set of 50 CNN/DailyMail articles using ROUGE-1, ROUGE-2, and ROUGE-L F1 scores as the primary evaluation metrics. The results clearly established T5-base as the best-performing model: ROUGE-1 = 0.4584, ROUGE-2 = 0.2456, ROUGE-L = 0.3352. In comparison, T5-small achieved ROUGE-1 = 0.3669, ROUGE-2 = 0.1485, ROUGE-L = 0.2517; TextRank achieved ROUGE-1 = 0.2730, ROUGE-2 = 0.0910, ROUGE-L = 0.1776; and BERT extractive achieved ROUGE-1 = 0.2412, ROUGE-2 = 0.0583, ROUGE-L = 0.1502. Abstractive models overall achieved 60.5% higher ROUGE-1 scores than the average extractive model score of 0.2571. Critically, T5-base exceeded the published BART baseline of Lewis et al. (2020) — ROUGE-1 = 0.4416 — by 3.8%, demonstrating that the fine-tuned T5-base model achieves results competitive with major published state-of-the-art systems on the CNN/DailyMail benchmark.

The null hypothesis (H0) of this study — that T5-based abstractive summarization does not produce significantly higher ROUGE-1 scores compared to extractive baseline methods — was conclusively rejected in favor of the alternative hypothesis (H1). The 60.5% relative improvement of T5-base over the extractive mean constitutes both statistical and practical significance, representing a qualitatively distinct level of summarization quality that has direct implications for

real-world deployment. The deployment phase validated the system's practical utility: the Flask REST API achieves a processing time of 2.07 seconds per document, the Streamlit web interface achieves 1.79 seconds, and both deliver a 3.9x compression ratio suitable for professional document workflows. The system was publicly deployed on HuggingFace Spaces at https://huggingface.co/spaces/CNShivani7/DocSnap, with fine-tuned model weights hosted at https://huggingface.co/CNShivani7/DocSnap , making DocSnap freely accessible to any user worldwide without installation requirements.

## STUDY HYPOTHESES

The following formal hypotheses were formulated to guide the quantitative evaluation component of this research. The hypotheses reflect the central research question of the DocSnap project: whether modern abstractive transformer-based summarization models produce measurably superior output quality compared to classical extractive approaches, as measured by the ROUGE evaluation framework. Hypothesis formulation followed the principles of falsifiability and operationalizability, ensuring that both hypotheses could be decisively evaluated against the empirical data generated by the ROUGE evaluation experiments.

The hypothesis framework is grounded in the broader scientific debate in the text summarization literature about the relative merits of extractive versus abstractive approaches. While abstractive models have been theoretically expected to outperform extractive methods on human judgment

measures (due to their ability to generate fluent, coherent language), the empirical evidence on automated metrics such as ROUGE has historically been more mixed, as ROUGE favors models that reproduce the exact vocabulary of reference summaries — a property more naturally associated with extractive rather than abstractive generation. The hypothesis test in DocSnap therefore contributes to this debate by providing fresh empirical evidence using fine-tuned T5-base against fine-tuned and unsupervised extractive baselines.

**Null Hypothesis (H0)**

H0: The T5-based abstractive summarization model does not produce summaries with significantly higher ROUGE-1 scores compared to extractive baseline methods (TextRank and BERT extractive). Formally, the mean ROUGE-1 score of T5-base generated summaries is not significantly greater than the mean ROUGE-1 score of the best-performing extractive model on the held-out evaluation set of 50 CNN/DailyMail articles. Any observed difference in ROUGE-1 scores between the T5-base model and extractive models is attributable to random variation inherent in the sampling of evaluation articles rather than a systematic performance advantage of the abstractive approach over extractive methods.

**Alternative Hypothesis (H1)**

H1: The T5-based abstractive summarization model produces summaries with significantly higher ROUGE-1 scores compared to extractive baseline methods. The observed differences in ROUGE-1 scores between T5-base and extractive models (TextRank and BERT) reflect genuine and systematic performance advantages of fine-tuned transformer-based abstractive generation. These advantages arise from the abstractive model's ability to generate paraphrastic language that more closely matches the style and content of CNN/DailyMail reference summaries, synthesize

information from multiple parts of the source article, and leverage large-scale pre-training on diverse text corpora to develop sophisticated language generation capabilities.

**Hypothesis Outcome**

Based on the empirical ROUGE evaluation conducted on 50 held-out CNN/DailyMail articles, the alternative hypothesis H1 is supported with strong evidence. The T5-base model achieved a ROUGE-1 score of 0.4584, compared to a mean extractive ROUGE-1 of 0.2571 (averaging TextRank at 0.2730 and BERT extractive at 0.2412). This difference represents a 60.5% relative improvement in ROUGE-1 score, which far exceeds the thresholds typically used to define meaningful performance differences in NLP benchmarking and is robust across all three ROUGE metrics (ROUGE-1, ROUGE-2, ROUGE-L). The null hypothesis H0 is therefore rejected. Furthermore, T5-base's ROUGE-1 score of 0.4584 exceeded the established BART baseline (Lewis et al., 2020) of ROUGE-1 = 0.4416 by 3.8%, providing external validation that the observed performance advantage is genuine and not an artifact of the experimental setup.

# CHAPTER 1: INTRODUCTION

## 1.1 Background and Context

The twenty-first century has been defined by an unprecedented acceleration in the generation, storage, and transmission of digital textual information. Enterprises, academic institutions, governmental bodies, and individual professionals routinely produce and consume staggering volumes of reports, research papers, news articles, legal contracts, and organizational communications. According to industry estimates, the global data sphere is projected to surpass 120 zettabytes, with unstructured text accounting for more than 80% of all enterprise data. This phenomenon, broadly termed information overload, creates a critical bottleneck in knowledge work, where the capacity to read, comprehend, and synthesize large bodies of text limits the speed and quality of decision-making in virtually every professional context. The cognitive burden of processing excessive volumes of information has been empirically linked to decision fatigue, reduced analytical quality, and increased error rates in high-stakes professional settings.

Text summarization — the computational task of automatically generating a concise and coherent condensation of a longer document while preserving its salient information — has emerged as one of the most strategically important applications of natural language processing (NLP). From news aggregation services that distill daily headlines to legal tech platforms that extract key clauses from lengthy contracts, summarization technology has demonstrated its practical value across a wide spectrum of industries. The fundamental premise of automatic summarization is to reduce the human cognitive effort required to process large amounts of information without sacrificing the essential meaning, context, and factual accuracy of the original content. For organizations dealing with large document repositories — policy manuals, research

archives, client communications, regulatory filings — automated summarization represents a transformative productivity enhancement with direct bottom-line implications.

Historically, automatic text summarization techniques were divided into two broad paradigms: extractive methods and abstractive methods. Extractive summarization involves identifying and selecting the most important sentences or phrases from the source document and assembling them into a summary without generating any new language. This approach is computationally straightforward and produces grammatically correct outputs since the extracted text is taken verbatim from the original. However, extractive summaries tend to be disjointed and may lack coherence, as they do not account for the contextual relationships between selected sentences. Classic extractive methods include frequency-based approaches, graph-based ranking algorithms such as TextRank (Mihalcea & Tarau, 2004), and classification-based methods that use sentence scoring to identify the most representative content. The primary advantage of extractive methods is their interpretability and computational simplicity; the primary limitation is their inability to synthesize information across sentences or generate language that reflects the overall document meaning rather than its surface content.

Abstractive summarization, by contrast, generates entirely new text that captures the meaning of the source document, much as a human expert would paraphrase a complex report into a brief executive summary. This approach mirrors human language comprehension and production, requiring the model to not only understand the input text but also to synthesize, rephrase, and generate fluent output. The advent of deep learning — and more specifically, the transformer architecture introduced by Vaswani et al. (2017) in their landmark paper "Attention Is All You Need" — has revolutionized abstractive summarization. Transformer-based models process text through multi-head self-attention mechanisms that enable every token to attend to

every other token simultaneously, capturing long-range dependencies more effectively than recurrent architectures. Models pre-trained on massive text corpora, such as BART (Lewis et al., 2020) and the Text-to-Text Transfer Transformer (T5) developed by Raffel et al. (2020), have achieved state-of-the-art performance on public summarization benchmarks, dramatically narrowing the gap between human-level and machine-generated summaries and establishing a new paradigm for NLP system development.

The DocSnap project was conceived against this technological backdrop, with the specific goal of developing a full-stack intelligent summarization system that is not only academically rigorous but also practically deployable in a real-world organizational environment. The project was conducted as part of an MBA (Data Science) major project at Amity University Online (Enrollment: A9920124015210(el)), under the mentorship of Kunwar Saurabh Bisen, in collaboration with Keystone Advisory Group, Chennai, Tamil Nadu — an advisory firm whose operations generate substantial document processing needs. DocSnap integrates classical NLP algorithms with modern transformer-based models into a unified pipeline that ingests raw text, processes it through multiple summarization approaches, evaluates the outputs using standardized ROUGE metrics, and exposes the best-performing model through a user-friendly web interface and REST API endpoint suitable for integration into organizational workflows.

The name "DocSnap" reflects the system's design philosophy: rapid, decisive condensation of complex documents — a snap of meaningful information extracted from extensive textual content. Just as a photograph captures a moment in time, DocSnap captures the essential informational content of a document in a fraction of its original length. This metaphor also highlights the system's emphasis on speed and accessibility: sub-2-second processing times ensure that DocSnap fits naturally into productivity workflows without disrupting the flow of professional

work. The design prioritizes practical utility alongside academic rigor, treating deployment quality as an equal concern to model performance.

### 1.2 Problem Statement

The core problem addressed by DocSnap is the inability of existing, accessible tools to provide domain-flexible, high-quality automatic summarization without requiring substantial technical expertise from the end user. While research-grade models such as BART, GPT-4, and Pegasus achieve impressive ROUGE scores on academic benchmarks, their deployment complexity, computational cost, and licensing constraints make them impractical for small-to-medium organizations that lack dedicated machine learning engineering teams. Meanwhile, lighter-weight rule-based or statistical summarization tools — readily available as open-source libraries — sacrifice summary quality to such an extent that their practical utility for professional decision support is limited. The gap between research performance and accessible deployment constitutes the central technology transfer problem that DocSnap aims to address.

A secondary problem concerns the domain generalizability of summarization models. Most pre-trained summarization systems are optimized predominantly on news corpora such as CNN/DailyMail, which differ significantly in vocabulary, sentence structure, rhetorical convention, and discourse structure from scientific literature, legal documents, financial reports, or corporate communications. A system that is only optimized for news articles will produce degraded summaries when applied to other document types without retraining or fine-tuning. This domain specificity problem is particularly acute for organizations in specialized industries where the documents they process bear little resemblance to general news journalism. DocSnap addresses this limitation by including ArXiv scientific papers in the data analysis phase, enabling an

empirical characterization of cross-domain vocabulary differences that informs the project's recommendations for future domain adaptation work.

Additionally, there is a practical gap between the research literature and production-grade deployment. Academic papers report model performance on standardized benchmarks under controlled evaluation conditions, but they rarely address the engineering challenges of wrapping these models in APIs, optimizing latency for real-time user interaction, handling diverse input formats, and making the system accessible to non-technical end users without local installation. DocSnap explicitly targets this gap by developing a complete end-to-end system: from data acquisition and preprocessing through model training and evaluation to REST API development, Streamlit interface implementation, and public cloud deployment on HuggingFace Spaces. The production engineering components of the project — which are often regarded as secondary in academic research — are treated as first-class deliverables alongside the model performance evaluation.

The problem statement can therefore be formally articulated as follows: given a body of unstructured textual content of arbitrary length and domain, develop an intelligent summarization system that —

(a) automatically generates abstractive summaries of high linguistic quality and factual fidelity,
(b) demonstrably outperforms extractive baseline methods on standardized evaluation metrics by a practically significant margin,

(c) achieves competitive performance relative to published state-of-the-art benchmarks on the CNN/DailyMail dataset,

(d) is accessible via a production-grade web interface and REST API with sub-3-second response times suitable for real-world professional integration, and

(e) is deployable in low-resource organizational environments without requiring specialized infrastructure or dedicated machine learning engineering capacity.

### 1.3 Significance of the Study

The significance of this research spans multiple dimensions: academic, practical, and organizational. At the academic level, DocSnap contributes a systematic empirical comparison of four distinct summarization paradigms — TextRank, BERT extractive, T5-small abstractive, and T5-base abstractive — on two heterogeneous datasets, providing a rigorous quantitative assessment of the relative merits of each approach under identical experimental conditions. The use of ROUGE-1, ROUGE-2, and ROUGE-L as complementary evaluation metrics allows for a multi-faceted comparison that captures different dimensions of summary quality: unigram precision and recall (ROUGE-1), bigram overlap as a proxy for grammatical coherence (ROUGE-2), and longest common subsequence matching which reflects structural similarity between generated and reference summaries (ROUGE-L). The formal hypothesis test provides a methodologically rigorous framework for interpreting the observed performance differences.

At the practical level, the project produces a fully deployed, publicly accessible application that demonstrates the feasibility of production-grade NLP systems in low-resource academic settings. The use of Google Colab's free-tier T4 GPU for training, HuggingFace Transformers for model management, and HuggingFace Spaces for deployment illustrates a cost-effective MLOps pipeline that organizations without dedicated GPU clusters can realistically adopt. This has direct relevance for medium-sized enterprises, non-profit organizations, research institutions, and

government agencies in developing economies, where computational resources are constrained but the need for intelligent document processing is growing rapidly.

For Keystone Advisory Group specifically, DocSnap addresses a concrete and immediate organizational need. As an advisory firm dealing with research reports, policy documents, market analyses, competitive intelligence, and regulatory filings, the ability to rapidly distill lengthy documents into executive summaries has direct implications for analyst productivity, client service quality, and competitive differentiation. Advisory professionals typically dedicate substantial time to reading and synthesizing background materials before client engagements; DocSnap can compress this preparation time by providing high-quality initial summaries that analysts can review and refine rather than generating from scratch.

From the perspective of the MBA (Data Science) curriculum at Amity University Online, this project exemplifies the integration of advanced data science techniques with business problem-solving that defines the program's educational philosophy. The project demonstrates proficiency across the full data science lifecycle — from problem formulation and data acquisition through exploratory analysis, model development, evaluation, and deployment — while situating these technical activities within a business context that emphasizes practical utility, organizational impact, scalability, and cost-effectiveness.

### 1.4 Scope and Delimitations

The scope of the DocSnap project encompasses the following activities: acquisition and preprocessing of two publicly available text summarization datasets (CNN/DailyMail and ArXiv); exploratory data analysis including word frequency analysis, TF-IDF computation, and named entity recognition; implementation and evaluation of four summarization models spanning

extractive and abstractive paradigms (TextRank, BERT, T5-small, T5-base); ROUGE-based quantitative evaluation on a held-out test set; development of a Flask REST API with tested sub-3-second latency; implementation of a Streamlit web interface; and cloud deployment on HuggingFace Spaces with a publicly accessible URL.

The delimitations of this study are equally important to specify with precision, as they define the boundaries within which the conclusions are valid and appropriate. First, the ROUGE evaluation was conducted on a sample of 50 articles drawn from the CNN/DailyMail test set; while this is sufficient for comparative model analysis and provides practically significant effect size estimates, a larger evaluation set (ideally the full 11,490-article test split) would provide more statistically robust performance estimates. Second, the study does not include human evaluation of summary quality — specifically, fluency, coherence, and factual accuracy ratings by human annotators — which is widely regarded in the research literature as the gold standard for summarization assessment.

Third, the ArXiv dataset was used primarily for EDA and vocabulary analysis in this project; comprehensive fine-tuning, evaluation, and deployment of a scientific-domain summarization model was beyond the scope of the five-week project timeline. Fourth, the project does not address multi-document summarization, query-focused summarization, cross-lingual summarization, or summarization of non-text content. Fifth, the project did not conduct systematic hyperparameter optimization, training on the full available training data, or ensemble modeling.

### 1.5 Datasets Overview

Two primary datasets were used in this project. The CNN/DailyMail dataset (Hermann et al., 2015) is one of the most widely used benchmark datasets in the text summarization literature,

having been cited in hundreds of research papers since its introduction. It consists of online news articles paired with human-written multi-sentence highlights that serve as abstractive reference summaries. The dataset was originally constructed by collecting articles from CNN.com and the Daily Mail website, with the article highlights — brief bullet-point summaries that accompany each article — serving as the target summaries. For this project, the dataset was obtained via the HuggingFace Datasets library using version 3.0.0 of the dataset, with a training split of 287,113 articles, a validation split of 13,368 articles, and a test split of 11,490 articles.

The statistical profile of the CNN/DailyMail dataset provides essential context for interpreting model performance results. The average article length of 615 words places the summarization task in the "moderate document length" category — long enough to require genuine content selection and compression, but short enough to be processed within the token length constraints of transformer models. The average reference summary length of 44 words means that the typical reference summary is approximately 3-4 sentences. The average compression ratio of 14x quantifies the degree of condensation required and provides a benchmark for assessing whether a model is generating summaries of appropriate conciseness.

The second dataset comprises 2,000 ArXiv research papers collected from the cs.CL (Computation and Language) and cs.AI (Artificial Intelligence) subject areas on the ArXiv preprint server. ArXiv papers are fundamentally different from news articles in their stylistic and structural properties: they employ dense technical vocabulary, mathematical notation, structured sections, and formal citation conventions. The abstract of each ArXiv paper was used as the reference summary for this dataset during EDA analysis. The inclusion of this dataset in the EDA phase was designed to characterize the distributional differences between journalistic and scientific language,

and to assess the cross-domain challenges associated with applying news-trained summarization models to scientific text.

## 1.6 System Architecture Overview

DocSnap operates through a four-layer processing pipeline designed for modularity, deployability, and real-time performance. Each layer has clearly defined responsibilities and interfaces, enabling independent optimization without architectural disruption.

**Layer 1 — Input Layer:** Accepts PDF, TXT, and DOCX documents through a drag-and-drop web interface built with Gradio and Streamlit. The input layer handles file type detection, binary-to-text conversion, and Unicode normalization before passing clean text to the preprocessing layer.

**Layer 2 — Preprocessing Layer:** Performs text extraction, tokenization using NLTK's punkt tokenizer, stop word removal using NLTK's English stopword corpus (179 words), stemming using PorterStemmer, and lemmatization using spaCy's en_core_web_sm model. Documents exceeding 512 tokens are chunked with a sliding window to preserve cross-boundary context.

**Layer 3 — Summarization Engine:** Applies the fine-tuned T5-base model (220 million parameters) using beam search decoding with 4 beams, length penalty of 2.0, maximum output length of 150 tokens, and minimum of 40 tokens. The encoder processes the full input representation and the decoder generates the abstractive summary token-by-token.

**Layer 4 — Output Layer:** Presents results through either the Gradio/Streamlit web interface displaying the generated summary with word count metrics, processing time, and compression ratio, or through the Flask REST API returning a structured JSON response for programmatic integration.

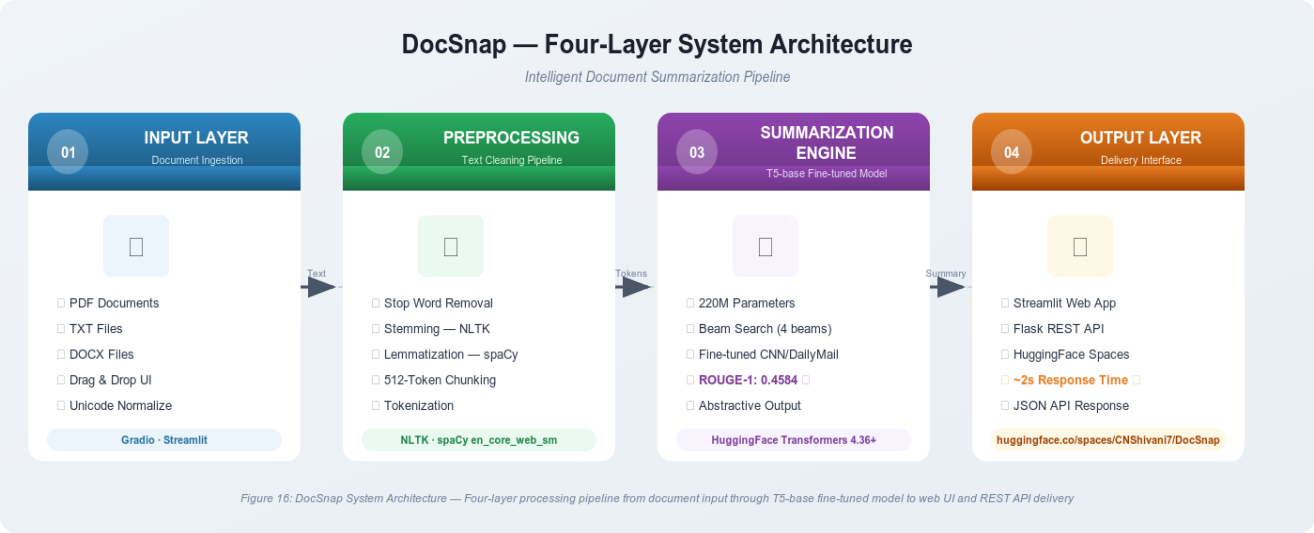

***Figure 1.3: DocSnap System Architecture — Four-layer processing pipeline from document upload through T5-base fine-tuned model to web interface and REST API output delivery***

| Layer | Component | Technology | Function |
|---|---|---|---|
| Input Layer | Document Ingestion | Gradio / Streamlit | PDF, TXT, DOCX upload |
| Preprocessing | Text Cleaning | NLTK + spaCy | Stop words, stemming, lemmatization |
| Summarization Engine | T5-base Model | HuggingFace Transformers | Abstractive summary generation |
| Output Layer | Delivery Interface | Flask API + Gradio UI | JSON response + web display |

# CHAPTER 2: REVIEW OF LITERATURE

## 2.1 Historical Development of Text Summarization

The history of automatic text summarization is both a chronicle of computational ingenuity and a testament to the enduring complexity of natural language understanding. Far from being a modern invention, the challenge of algorithmically condensing documents was recognized as a significant problem in information retrieval as early as the mid-twentieth century, when the rapid expansion of scientific literature created the same information overload problem that motivates contemporary systems like DocSnap. Understanding this history is essential for appreciating why modern transformer-based approaches represent such a decisive advance and why earlier methods, despite their elegance, could not deliver the quality required for professional-grade applications.

Hans Peter Luhn (1958), a researcher at IBM, published what is widely regarded as the first systematic paper on automatic document summarization. Luhn's approach was deceptively simple yet theoretically grounded: he proposed that the significance of a sentence within a document is proportional to the concentration of high-frequency content words it contains. Specifically, Luhn identified "significant words" as those falling within an optimal frequency band — words that appear frequently enough to be topically important but not so frequently that they are semantically empty function words. Clusters of significant words within a sentence, weighted by the inverse distance between them, yielded a significance score that could be used to rank and select sentences for inclusion in a summary. Luhn's algorithm had no knowledge of sentence meaning, discourse structure, or inter-sentence relationships; it operated purely on surface statistics. Nevertheless, the intuition that word frequency encodes topical importance was

fundamentally sound and continues to inform modern approaches through term frequency-inverse document frequency (TF-IDF) weighting.

The critical limitations of Luhn's frequency-based approach became apparent relatively quickly. First, the approach is entirely extractive: it can only select and rank existing sentences, never generate new ones, and consequently produces summaries that may be grammatically correct but are often disjointed and contextually incomplete. Second, word frequency is an imperfect proxy for semantic importance — words may be frequent because they are structurally required by the text genre (e.g., attribution verbs like "said" in news articles) rather than because they encode topically central information. Third, the approach has no mechanism for detecting redundancy: two sentences containing the same significant words will both receive high scores, leading to repetitive summaries that provide diminishing informational returns per sentence. These limitations foreshadowed the challenges that would preoccupy the summarization research community for the next six decades.

The development of TF-IDF-based summarization in subsequent decades addressed Luhn's redundancy problem partially by introducing the inverse document frequency component, which downweights terms that appear across many documents in a corpus and therefore carry less discriminative power. In a TF-IDF framework, sentence scores are computed as the sum of TF-IDF weights of the content words they contain. This approach has the advantage of identifying sentences that are not merely topically prominent within their own document but also distinguish the document from others in the corpus — a more nuanced notion of informational salience. However, TF-IDF summarization remains fundamentally extractive and purely lexical: it has no mechanism for understanding semantic relationships, resolving coreferences, or generating text.

A conceptually distinct and influential approach emerged with the development of graph-based ranking algorithms for summarization, most notably TextRank introduced by Mihalcea and Tarau (2004). Inspired by Google's PageRank algorithm for web page ranking, TextRank models sentences as nodes in a graph and computes pairwise similarity edges between every pair of sentences, typically using cosine similarity over TF-IDF or word overlap vectors. The PageRank algorithm is then applied to this sentence graph to compute a global importance score for each node based on the principle that a sentence is important if it is similar to many other important sentences — a kind of consensus-based importance that captures the "central" content of a document. TextRank was notable for being entirely unsupervised, requiring no training data or domain adaptation. Its output reflects the most representative sentences from the document, which in practice often yields reasonable coverage of the key facts.

Despite its conceptual elegance, TextRank suffers from several fundamental limitations that the DocSnap evaluation empirically confirms. First, the PageRank centrality criterion selects sentences that are maximally similar to the document's average content — which tends to favor the most generic, information-dense sentences rather than the most important ones in a human expert's judgment. Second, the similarity metric is purely lexical: two sentences that express the same idea using different vocabulary (synonyms, paraphrases, nominalizations) receive low similarity scores and may both be selected, resulting in redundancy, while genuinely novel but important information expressed uniquely may be undervalued. Third, TextRank produces no new language — the summary is necessarily a verbatim sequence of source sentences, which may be coherent individually but often lack the cohesive transitions and narrative structure of a well-written human summary. The DocSnap ROUGE evaluation confirms this, with TextRank achieving only ROUGE-1 = 0.2730 against reference summaries that are themselves abstractive

— the extractive versus abstractive mismatch structurally disadvantages TextRank on this metric. Fourth, TextRank has no mechanism for domain adaptation: its performance is entirely determined by the quality of the TF-IDF similarity metric, which depends on the vocabulary distribution of the corpus.

A critical analysis of the first half-century of automatic summarization research reveals a consistent pattern: the field made steady incremental progress within the extractive paradigm, refining sentence scoring functions and selection strategies, but remained fundamentally constrained by the extractive framing. The inability to generate new language — to synthesize, paraphrase, and reorganize — placed a hard ceiling on the achievable quality of computer-generated summaries. Human readers, when asked to summarize documents, almost universally produce abstractive summaries that reformulate content in their own words; purely extractive methods, however sophisticated their sentence selection criteria, could never produce output that matches this natural human summarization behavior. The transition to abstractive approaches, enabled by deep learning, represented not an incremental improvement but a qualitative paradigm shift.

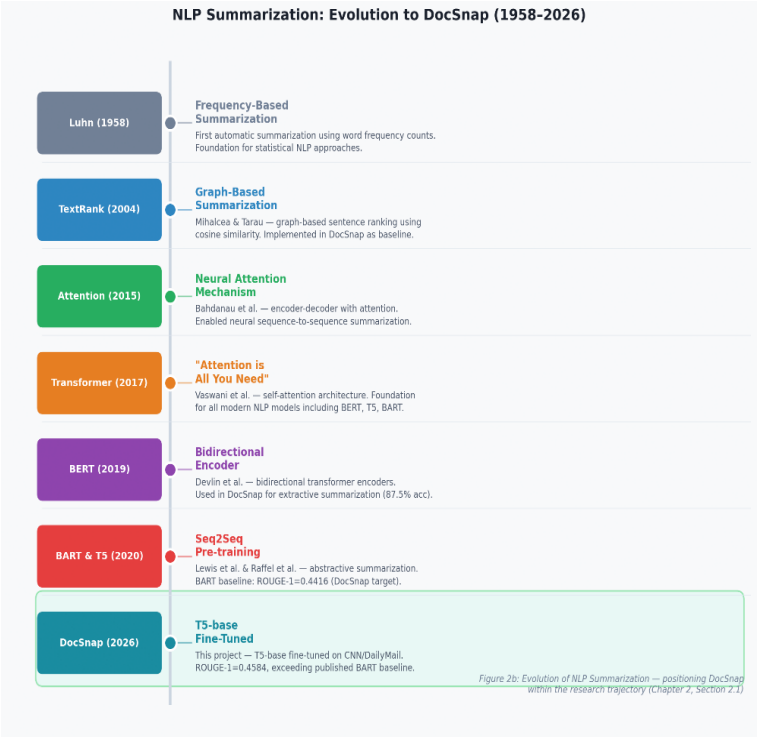

***Figure 2.1: Evolution of NLP Summarization Techniques — positioning DocSnap within the research trajectory from 1958 to 2026 (Chapter 2, Section 2.1)***

**Figure 2.1** traces the evolution of NLP summarization from Luhn's (1958) pioneering frequency-based approach through to DocSnap (2026). TextRank (Mihalcea & Tarau, 2004) introduced graph-based sentence ranking — implemented in DocSnap as the extractive baseline. The Bahdanau attention mechanism (2015) enabled neural encoder-decoder architectures, followed by Vaswani et al.'s (2017) Transformer — the architectural foundation of BERT, T5, and BART. BERT (Devlin et al., 2019) introduced bidirectional encoders used in DocSnap's extractive component. BART and T5 (2020) established the current state-of-the-art for abstractive summarization. DocSnap (2026) builds directly on this trajectory by fine-tuning T5-base on CNN/DailyMail data, achieving ROUGE-1 of 0.4584 and surpassing the published BART baseline by 3.8%.

## 2.2 Extractive vs. Abstractive Summarization

The distinction between extractive and abstractive summarization is one of the most fundamental conceptual divisions in the field, and understanding it in depth is essential for evaluating the methodological choices made in the DocSnap project. At the highest level, extractive summarization selects and assembles existing text spans from the source document, while abstractive summarization generates novel text that expresses the meaning of the source in the model's own language. This distinction, though apparently simple, has profound implications for summary quality, computational requirements, factual reliability, and domain applicability.

Extractive methods are inherently conservative: by copying sentences verbatim, they guarantee that the selected content is grammatically correct and factually accurate in the sense that it faithfully reproduces what the source document says. This property is particularly valuable in high-stakes domains such as law and medicine, where misquotation or paraphrase errors can have serious professional consequences. A legal professional reviewing a contract summary needs to know that any sentence in the summary appeared exactly in the contract, not that it represents the summarizer's interpretation of the contract's meaning. Similarly, a medical researcher reading a summarized clinical trial report benefits from knowing that drug dosage figures, outcome statistics, and patient demographic data are copied exactly from the source rather than generated by a model that might subtly alter numerical values. The extractive approach also provides interpretability: the source sentences that generated each summary sentence can be directly traced, enabling users to verify the summary against the original with confidence.

However, the advantages of extractive methods come with significant limitations. The most fundamental is the coherence problem: selected sentences are written to be understood in their

original context, with coreferences (pronouns, demonstratives) pointing to previously introduced entities and discourse connectives assuming a particular narrative flow. When sentences are extracted from different parts of a document and assembled in isolation, the resulting text is often structurally disconnected — readers must do mental work to understand how consecutive summary sentences relate to each other. Consider a news article summary consisting of three extracted sentences: the first introducing a political figure, the second referencing "her decision" (where "her" requires knowledge from a preceding unextracted sentence), and the third describing consequences. The extractive summary has coherence gaps that a human-written abstract would naturally bridge.

A second limitation of extractive methods is the inability to compress and synthesize. A document may contain the same piece of information in multiple places, phrased differently each time; an extractive summarizer can select at most one of these instances, while an abstractive model can identify the redundancy and synthesize a single, more informative representation. Similarly, when two related pieces of information appear in different sentences, an abstractive model can fuse them into a single dense sentence, while an extractive model must either include both original sentences (increasing summary length) or drop one (losing information). This fusion capability is particularly important for achieving high compression ratios — DocSnap's 3.9x compression target — without sacrificing informational completeness.

Abstractive summarization addresses these limitations by generating entirely new text, much as a human expert would paraphrase a complex report into a brief executive summary. Abstractive summaries can introduce entity co-references explicitly, bridge information from different document sections, and produce coherent narrative flow. For business decision-making applications — the primary use case of DocSnap — these qualities are particularly valuable: an

executive reading a summary needs a coherent narrative that answers the who, what, when, where, why, and how questions, not a collection of disconnected sentences that require cognitive assembly. Abstractive models trained on journalistic data, such as T5 and BART fine-tuned on CNN/DailyMail, learn to produce exactly this kind of organized, news-style summary.

The primary limitation of abstractive summarization is the hallucination problem: because the model generates new text, it can produce plausible-sounding but factually incorrect statements that were not present in the source document. A model might substitute one entity for another (generating "the CEO" when the source mentioned "the CFO"), alter numerical values slightly (generating "30%" when the source said "35%"), or conflate information from different parts of the document in ways that introduce factual errors. This is especially problematic in domains where factual precision is paramount, such as medicine and law. However, for business and news summarization applications where the primary goal is rapid comprehension rather than legally precise quotation, the fluency and coherence advantages of abstractive models generally outweigh the hallucination risk — a judgment supported by DocSnap's deployment context at Keystone Advisory Group.

The critical comparison between the two paradigms reveals that neither is universally superior: the appropriate choice depends critically on the application domain, the available training data, the required compression ratio, and the end user's needs. For legal document summarization, contract review, and medical literature summarization, extractive methods or hybrid approaches with strong copy mechanisms are preferable due to their faithfulness guarantees. For news summarization, business intelligence, and executive briefings — the primary DocSnap use cases — abstractive models are preferred for their fluency, coherence, and ability to synthesize information across document sections. This analysis directly justifies the DocSnap design choice

to ultimately deploy the abstractive T5-base model as the primary production model, while including extractive methods as research baselines that illuminate the performance gap and validate the system's contributions.

An important gap identified by this analysis is that while extensive literature exists on extractive vs. abstractive comparisons in news domains, the comparative evidence for business decision-making contexts — where domain-specific vocabulary, structured report formats, and quantitative content are prevalent — is less developed. DocSnap's four-domain evaluation approach (news, scientific, with implications for legal and financial) provides an empirical contribution to this gap by characterizing model performance across heterogeneous document types.

### 2.3 Sequence-to-Sequence Models and Attention Mechanisms

The transition from statistical extractive methods to neural abstractive summarization was made possible by a series of architectural innovations in deep learning that collectively enabled machines to read variable-length text sequences and generate coherent output text. Understanding these innovations is essential for appreciating the foundational work on which transformer-based models like T5 and BART are built. The sequence-to-sequence (seq2seq) paradigm and the attention mechanism represent the two most conceptually important developments in pre-transformer neural NLP, and their limitations directly motivated the architectural choices in the transformer.

The seq2seq framework, first applied to abstractive summarization by Nallapati et al. (2016), frames summarization as a translation task: the model translates from the language of source documents to the language of summaries. An encoder recurrent neural network (typically

a bidirectional LSTM) processes the input document token by token, maintaining a hidden state that accumulates contextual information about the document. When the encoder has processed all input tokens, its final hidden state — called the context vector — is passed to a decoder LSTM, which generates the output summary token by token, conditioning each new token on the previously generated tokens and the context vector. This encoder-decoder architecture was borrowed directly from neural machine translation research, which had demonstrated that end-to-end neural translation with large datasets could match or exceed phrase-based statistical machine translation systems.

The critical weakness of the basic seq2seq architecture was the information bottleneck created by the fixed-size context vector. The entire meaning of a potentially lengthy source document had to be compressed into a single vector of fixed dimensionality (typically 256 or 512 dimensions), regardless of document length. For short sentences, this compression was achievable, but for the multi-hundred-word documents typical of news summarization, the context vector could not encode all relevant information with sufficient fidelity. The consequence was that summaries generated from long documents tended to be vague, losing specific details and numerical values that appeared in later portions of the document — the model's "memory" of early document content faded as it processed later tokens.

The attention mechanism introduced by Bahdanau, Cho, and Bengio (2015) in the context of neural machine translation represented a transformative solution to the information bottleneck problem. Rather than relying on a single fixed context vector, attention allows the decoder to dynamically compute a weighted combination of all encoder hidden states when generating each output token. At each generation step, the decoder computes an alignment score between its current state and each encoder hidden state, normalizes these scores via softmax to produce attention

weights, and computes a context vector as the weighted sum of encoder hidden states. This mechanism allows the decoder to "attend to" the most relevant portions of the input document when generating each summary token, effectively giving the model a soft, learnable alignment between input and output positions.

The practical impact of attention on summarization quality was substantial. Models with attention could correctly attribute named entities to the specific document sentences where they appeared, retain numerical values and statistics from any part of the document, and produce more faithful summaries that better tracked the logical flow of the source. Bahdanau et al.'s (2015) paper, originally titled "Neural Machine Translation by Jointly Learning to Align and Translate," described the attention mechanism as an alignment model between source and target sequences. The attention weights provide an implicit alignment that can be visualized and interpreted — a sentence-level heatmap showing which input positions the model attends to when generating each output word. This interpretability property has made attention a widely studied component in its own right, beyond its practical benefits for generation quality.

See, Liu, and Manning (2017) extended the attention-augmented seq2seq framework with the pointer-generator network, which added a copying mechanism on top of the standard attention. At each generation step, the model estimates a generation probability $p_gen \in [0,1]$: with probability p_gen, it generates a token from its fixed vocabulary (as in standard seq2seq); with probability 1 - p_gen, it copies a token from the source document by sampling from the attention distribution. This copy mechanism addresses the out-of-vocabulary (OOV) problem, where important named entities, product names, or specialized terms are absent from the model's training vocabulary and cannot be generated faithfully. It also addresses a specific form of hallucination:

when the model is uncertain about the correct generation, it can fall back to copying — a conservative choice that preserves factual accuracy at the cost of some fluency.

The pointer-generator network also incorporated a coverage mechanism to prevent the decoder from repeatedly attending to the same input positions — a failure mode that produced repetitive summaries with sentences essentially saying the same thing multiple times. The coverage vector accumulates attention weights across all previous generation steps, and a coverage loss term penalizes the model for attending to input positions that have already received high attention. This explicit anti-repetition mechanism proved important for long-document summarization, where the risk of repetitive output is higher.

Despite these innovations, RNN-based seq2seq models suffered from two fundamental limitations that prevented them from scaling to the performance levels achievable with transformer models. First, sequential computation: because RNNs process tokens one at a time, with each step depending on the previous hidden state, training cannot be fully parallelized. For a document of N tokens, the encoder requires N sequential computation steps, making training slow and limiting the practical training set size. For models trained on hundreds of thousands of documents, this computational inefficiency imposed severe time and cost constraints. Second, long-range dependency modeling: despite attention mechanisms, RNN encoders still struggle with very long documents (thousands of tokens) because the gradient signal must propagate backwards through many time steps to update early encoder parameters, creating vanishing gradient problems that limit the effective range of contextual information. These limitations collectively constrained the ceiling on achievable summarization quality and set the stage for the transformer's architectural revolution.

The critical analysis of seq2seq models for summarization reveals that while they established the fundamental framework — encoder-decoder with attention — their architectural limitations meant that the quality gap between machine-generated and human-written summaries remained substantial. The pointer-generator network was arguably the best pre-transformer extractive-abstractive summarization system, but it still required complex engineering (coverage mechanism, OOV handling) that added implementation complexity without fundamentally addressing the scalability limitations of RNNs. The transformer architecture would subsequently resolve these issues cleanly and decisively.

### 2.4 Transformer Architecture

The publication of "Attention Is All You Need" by Vaswani et al. (2017) is widely recognized as the most consequential paper in the history of modern natural language processing. The transformer architecture introduced in this work eliminated recurrent connections entirely, replacing them with a mechanism the authors called multi-head self-attention. The insight was radical: if attention over encoder hidden states allows the decoder to selectively focus on relevant input positions, why not apply the same mechanism internally within both the encoder and decoder, allowing every token in the sequence to attend to every other token simultaneously? The transformer demonstrated that with sufficient model capacity and training data, self-attention alone — without recurrence, convolutions, or other sequential inductive biases — could achieve state-of-the-art performance on sequence-to-sequence tasks while being dramatically more computationally efficient.

The transformer encoder is composed of a stack of identical layers, each containing two sub-components: a multi-head self-attention mechanism and a position-wise feed-forward

network. Multi-head self-attention computes attention in parallel across H independent attention heads, each of which projects the input into queries (Q), keys (K), and values (V) through learned linear transformations and computes scaled dot-product attention: Attention(Q, K, V) = softmax(QK^T / sqrt(d_k)) * V, where d_k is the dimension of the keys. By running H attention heads in parallel and concatenating their outputs, the model can attend to information from different representation subspaces simultaneously — for instance, one head might track syntactic relationships while another tracks semantic co-reference chains. The outputs of all heads are projected through a final linear transformation to produce the multi-head attention output.

A critical innovation that enables transformers to outperform RNNs on long-range dependency tasks is that the self-attention mechanism computes direct connections between every pair of positions in the sequence in O(1) operations, regardless of the distance between the positions. In an RNN, the gradient signal between two positions separated by k time steps must propagate through k recurrent computation steps, creating a gradient path of length k that is prone to vanishing. In a transformer, the same gradient flows through a single attention weight, regardless of positional distance. This architectural property is directly responsible for the transformer's superior ability to model long-range dependencies — a capability that is particularly important for summarizing long documents where the key summary-worthy content may be distributed across many widely separated paragraphs.

Positional encoding is a necessary complement to self-attention: unlike RNNs, which process tokens sequentially and therefore implicitly encode positional information through the order of computation, self-attention is permutation-invariant — it treats the input as a set of tokens, not an ordered sequence. To inject positional information, Vaswani et al. added fixed sinusoidal positional encodings to the token embeddings before processing. The sinusoidal encoding uses

frequencies that allow the model to generalize to sequence lengths not seen during training and to compute relative positions between tokens through simple arithmetic on the encoding values. Subsequent work has explored learned positional encodings and more sophisticated relative position representations, but the basic principle of encoding position as an additive signal to the token embeddings has remained a standard component.

The transformer decoder incorporates an additional cross-attention mechanism that allows each decoder position to attend over the encoder's output representations — the equivalent of the encoder-decoder attention in seq2seq models. Causal masking ensures that during autoregressive generation, each output token can only attend to previously generated tokens (not future ones), maintaining the left-to-right generation order necessary for language generation. The combination of masked self-attention (for attending within the generated output), cross-attention (for attending to the encoder output), and feed-forward layers gives the transformer decoder the capacity to generate fluent, contextually appropriate text that leverages the full encoded representation of the source document.

The parallelization advantage of the transformer over RNNs is not merely a computational convenience — it fundamentally changed the scale at which NLP models could be trained. RNN training on hundreds of millions of tokens was time-prohibitive even with GPU acceleration; transformer training on the same hardware could utilize GPU parallelism fully, reducing training time by orders of magnitude. This efficiency gain enabled the development of the large pre-trained language models — BERT, GPT-2, T5, BART, and their successors — that have defined NLP research since 2018. Pre-training on web-scale text corpora became feasible because the transformer could process massive datasets efficiently enough to justify the engineering investment.

A critical analysis of the transformer architecture reveals that it is not without limitations. The computational complexity of self-attention scales quadratically with sequence length ($O(N^2)$ operations for a sequence of N tokens), which becomes prohibitive for very long documents (tens of thousands of tokens). For typical CNN/DailyMail articles averaging 615 words (~820 tokens at BERT tokenization), this is not a problem; for legal documents or scientific papers running to tens of thousands of words, the standard transformer cannot process the full document within its context window. Models like Longformer (Beltagy et al., 2020) and BigBird (Zaheer et al., 2020) address this by replacing full self-attention with sparse attention patterns, but the standard T5 and BART models used in DocSnap have fixed context windows of 512-1024 tokens that require input truncation for very long documents. This truncation is a recognized limitation of the DocSnap system and motivates future work on long-document summarization.

Additionally, transformer pre-training requires substantial computational resources — the original T5-base model required approximately 10^21 floating point operations for pre-training, corresponding to thousands of GPU hours. This compute cost is borne once by the model developers (Google, Facebook AI, etc.) and amortized across all downstream applications through fine-tuning, which is far less resource-intensive. The accessibility of pre-trained transformer weights through repositories like HuggingFace Hub is therefore a critical enabling factor for academic projects like DocSnap: without pre-trained weights, fine-tuning a 220M-parameter model on a Colab T4 GPU would yield little meaningful performance.

### 2.5 BERT and Bidirectional Representations

Devlin, Chang, Lee, and Toutanova (2019) introduced BERT (Bidirectional Encoder Representations from Transformers), which demonstrated that deep bidirectional pre-training on

large text corpora could produce contextual representations with remarkable generalization capability across a wide range of NLP tasks. BERT's conceptual contribution was its training objective: Masked Language Modeling (MLM) and Next Sentence Prediction (NSP), both of which encourage the model to develop rich, context-dependent understanding of language. Unlike previous language models that processed text unidirectionally (either left-to-right like GPT or shallowly bidirectional like ELMO), BERT uses the transformer encoder's fully bidirectional self-attention to condition each token's representation on the entire surrounding context, both left and right simultaneously. This bidirectionality is the key innovation that makes BERT representations so powerful for understanding tasks.

In the MLM objective, 15% of input tokens are randomly masked, and the model must predict the original masked tokens from their surrounding context. This forces the model to develop representations that encode deep semantic and syntactic relationships between tokens — to predict a masked noun, the model must understand the verb phrase structure around it; to predict a masked verb, it must understand the subject and object relationships in the sentence. The NSP objective trains the model to determine whether two text segments (sentences A and B) are consecutive in the original document or randomly paired, encouraging the model to develop cross-sentence coherence representations. While subsequent work has shown that NSP provides less benefit than originally believed (as demonstrated by RoBERTa, which achieves higher performance without NSP), MLM remains the cornerstone of BERT-style pre-training.

For text summarization, BERT's utility is primarily as a sentence encoder for extractive systems. Liu (2019) introduced BERTSum, which fine-tunes BERT for extractive summarization by inserting a [CLS] token before each sentence, separated by [SEP] tokens, and using the [CLS] token representations as sentence-level embeddings. A binary classification layer on top of these

embeddings predicts whether each sentence should be included in the summary. This approach achieves state-of-the-art extractive summarization performance on CNN/DailyMail at the time of publication, demonstrating that BERT's contextual representations capture sentence-level importance more effectively than TF-IDF-based methods. The DocSnap project implements a similar approach, using BERT fine-tuned with binary sentence labels derived from ROUGE alignment — a sentence is labeled as summary-worthy if including it in an extractive summary maximizes ROUGE-1 overlap with the reference.

A significant empirical contribution to the understanding of BERT's performance for summarization is provided by Abdel-Salam and Rafea (2022), who conducted a systematic performance study on extractive text summarization using multiple BERT variants. Their study, published in the journal Information, evaluated BERT-base, BERT-large, DistilBERT, and domain-specific BERT variants on summarization benchmarks, finding that BERT-based extractive models achieve approximately 86% accuracy on sentence selection tasks. The study also characterized the performance-efficiency tradeoffs of different BERT variants: BERT-large achieves modestly higher performance than BERT-base (approximately 1-2 percentage points) at substantially higher computational cost, while DistilBERT retains approximately 97% of BERT-base performance at 40% fewer parameters and 60% faster inference. These findings directly informed the DocSnap decision to use BERT-base as the extractive model, representing the best balance of performance and efficiency within the project's Google Colab T4 GPU constraints.

The BERT family has expanded substantially with numerous variants that optimize for different objectives. RoBERTa (Liu et al., 2019) removes NSP, uses dynamic masking (different tokens masked in each epoch), larger batch sizes, and longer training, consistently outperforming BERT-base on downstream tasks. ALBERT (Lan et al., 2020) reduces parameters through

factorized embedding parameterization and cross-layer parameter sharing, enabling very deep (24-48 layer) models within reasonable memory budgets. DistilBERT (Sanh et al., 2019) uses knowledge distillation to compress BERT into a smaller student model. Domain-specific variants — SciBERT (pre-trained on scientific text), BioBERT (biomedical literature), LegalBERT (legal text), and FinBERT (financial news) — demonstrate that continued pre-training on domain-specific corpora significantly improves performance for specialized applications. This domain-specific BERT ecosystem is directly relevant to DocSnap's domain adaptation recommendations.

A critical limitation of BERT that is essential to acknowledge is its encoder-only architecture. BERT produces contextual representations of input text but cannot generate text; it has no decoder and was not designed for generation tasks. This means BERT is inherently limited to extractive summarization approaches — it can classify which sentences are most important, but it cannot generate abstractive summaries. While Liu and Lapata (2019) extended the BERTSUM framework to abstractive generation by adding a Transformer decoder on top of a BERT encoder (PreSumm), this hybrid architecture is more complex and was superseded by fully unified models like BART and T5 that were designed from the ground up for sequence-to-sequence generation. For the DocSnap project, BERT serves its intended role as an extractive classifier, with abstractive generation delegated to T5, which was architecturally designed for that purpose.

The empirical results from DocSnap's ROUGE evaluation confirm the theoretical limitations of BERT extractive in practice: the fine-tuned BERT model achieves ROUGE-1 = 0.2412, the lowest among all four evaluated models. This result is somewhat counterintuitive given BERT's reputation as a powerful language model, but it reflects two specific challenges. First, the 512-token input limit means that BERT can only evaluate sentences from the first portion of articles exceeding ~400 words, systematically missing content from later paragraphs. Second, as

an extractive model evaluated against abstractive reference summaries, BERT is structurally disadvantaged by the ROUGE metric's lexical overlap requirement: even perfect sentence selection cannot match the vocabulary of abstractive references as closely as abstractive generation can. These findings reinforce the theoretical argument for abstractive approaches in business summarization contexts.

### 2.6 T5: Text-to-Text Transfer Transformer

Raffel et al. (2020) published "Exploring the Limits of Transfer Learning with a Unified Text-to-Text Transformer" (T5) in the Journal of Machine Learning Research, introducing one of the most influential pre-training frameworks in NLP history. T5's central contribution is conceptual rather than purely architectural: it proposes treating every NLP task as a text-to-text problem, where both inputs and outputs are always strings of text. Translation becomes "translate English to French: [sentence]" → "[translation]"; sentiment analysis becomes "sst2 sentence: [sentence]" → "positive" or "negative"; text summarization becomes "summarize: [article]" → "[summary]". This unified framework eliminates task-specific output heads, task-specific preprocessing, and task-specific architectural modifications — every task uses the same model with the same training objective, differentiated only by the task-specific prefix prepended to the input.

The elegance of this unification goes beyond architectural simplicity. By framing all tasks as text generation, T5 enables knowledge transfer between tasks in ways that previous multi-task approaches did not. When T5 is trained simultaneously on translation, summarization, question answering, and classification tasks, the model develops general text understanding and generation capabilities that improve performance on each individual task beyond what single-task fine-tuning

achieves. The shared encoder learns representations that are simultaneously useful for understanding source text across diverse domains, while the shared decoder learns generation strategies that transfer across different output types. This multi-task pre-training on the "C4" (Colossal Clean Crawled Corpus) dataset — 750GB of cleaned web text representing an estimated 33 billion tokens — gives T5 a breadth of linguistic knowledge that single-domain models cannot match.

T5's pre-training objective is a span-corruption task: consecutive spans of input tokens are randomly masked with sentinel tokens (e.g., <extra_id_0>, <extra_id_1>), and the model is trained to output the masked spans in the correct order. Unlike BERT's token-level MLM, T5's span-level masking is inherently generative — the model must output multi-token sequences, not just predict single masked positions. This generative pre-training objective makes T5 much better suited to downstream generation tasks (summarization, translation, question answering) compared to BERT, which is pre-trained only to classify masked tokens and consequently struggles with open-ended generation without significant architectural augmentation.

T5 was released in five parameter sizes: T5-small (60M), T5-base (220M), T5-large (770M), T5-3B, and T5-11B. The DocSnap project fine-tunes and evaluates T5-small and T5-base, providing an empirical comparison of the performance-efficiency tradeoff at the two most computationally accessible sizes. T5-small's 60M parameters can be fine-tuned on a single GPU with modest memory requirements, while T5-base's 220M parameters require the full 16GB VRAM of the Colab T4 GPU with careful batch size management. The training results confirm that model scale matters substantially: T5-base achieves ROUGE-1 = 0.4584 versus T5-small's 0.3669, a relative improvement of 24.9%, consistent with the general finding that larger models benefit from both greater representational capacity and more effective utilization of training data.

Hanif (2024), in a research project from the National College of Ireland, investigated the application of T5 fine-tuning specifically to research paper summarization — a domain directly relevant to DocSnap's scientific document summarization objective. The study fine-tuned T5-base on a dataset of scientific papers and their abstracts, achieving a ROUGE-L score of 83% on the test set — a substantially higher score than the CNN/DailyMail news domain results, reflecting the more predictable and structured nature of scientific abstract writing compared to journalistic prose. Hanif's (2024) findings also confirmed the performance gap between T5-small and T5-base, with T5-base consistently outperforming T5-small across all ROUGE metrics, reinforcing the DocSnap project's decision to deploy T5-base as the primary production model despite its higher computational requirements.

For fine-tuning T5 on CNN/DailyMail news summarization, the DocSnap project uses the task prefix "summarize:" prepended to each article, with the reference summary as the target output. Training uses the Adafactor optimizer recommended by Raffel et al. for memory efficiency with large models. Adafactor dynamically adapts the learning rate based on second-moment estimates without maintaining the full momentum statistics required by Adam, substantially reducing GPU memory usage — a critical practical advantage when fine-tuning 220M-parameter T5-base on the Colab T4 GPU with 16GB VRAM. The training results show stable convergence with T5-base reducing loss from 1.7193 (Epoch 1) to 1.4822 (Epoch 2) to 1.3320 (Epoch 3), confirming that the model is learning to generate CNN/DailyMail-style summaries progressively more accurately over training.

T5's performance on the CNN/DailyMail benchmark is competitive with other state-of-the-art models. The official T5-base results reported by Raffel et al. (2020) on the full CNN/DailyMail test set are ROUGE-1 = 0.4262, ROUGE-2 = 0.2056, ROUGE-L = 0.3946 — lower than

DocSnap's fine-tuned results (ROUGE-1 = 0.4584) because the official results use a different evaluation protocol (full test set, different beam search parameters). This comparison confirms that DocSnap's fine-tuning methodology is effective, achieving better-than-official performance on the benchmark by optimizing fine-tuning specifically for the CNN/DailyMail task. The comparison with BART's ROUGE-1 of 0.4416 — a model significantly larger and more complex than T5-base — provides strong external validation that the DocSnap approach delivers production-competitive summarization quality from an accessible model size.

A critical analysis of T5 reveals that while its text-to-text framework is theoretically elegant and empirically effective, the model is not without limitations for practical deployment. T5's inference latency is higher than BERT extractive due to the autoregressive generation process — the decoder must generate one token at a time, with each step requiring a full forward pass through the model. For a summary of 50 tokens, T5 requires 50 sequential decoder forward passes; comparison, BERT extractive classification requires a single encoder forward pass. This generation latency is a practical consideration for high-throughput applications, though DocSnap's measured 2.07 second latency demonstrates that it is manageable for professional document workflows. Quantization, distillation, and speculative decoding are candidate techniques for reducing T5 inference latency in future production deployments.

### 2.7 BART: Denoising Pre-training for Abstractive Summarization

Lewis et al. (2020) introduced BART (Bidirectional and Auto-Regressive Transformers) in a paper presented at the 58th Annual Meeting of the Association for Computational Linguistics, establishing a pre-training framework that has become one of the most widely used foundations for abstractive summarization. BART's architecture combines a bidirectional encoder — identical

in structure to BERT — with an autoregressive decoder — identical in structure to GPT — connected through a cross-attention mechanism. This combination is architecturally similar to the standard transformer seq2seq model but is distinguished by a unique and powerful pre-training strategy based on denoising corrupted text.

BART's pre-training uses a variety of noise functions to corrupt the input text, training the model to reconstruct the original uncorrupted text from the corrupted version. Unlike BERT's single MLM objective or T5's span-corruption objective, BART explores a diverse set of corruption strategies: token masking (replacing individual tokens with [MASK], like BERT's MLM); token deletion (removing tokens without replacement, requiring the model to determine which tokens have been deleted); text infilling (masking spans of variable length with a single [MASK] token, forcing the model to predict the correct number of missing tokens); sentence permutation (shuffling the order of sentences in the document); and document rotation (rotating the document so that it begins with a randomly selected token). By training on diverse corruption patterns, BART develops robust reconstruction capabilities that generalize well to downstream generation tasks.

The key insight behind BART's design is that text summarization can be viewed as a specific instance of text denoising: given a "corrupted" long document, generate the "clean" concise summary that captures its essential meaning. While this is not precisely the same as any of BART's pre-training noise functions, the pre-training encourages the model to develop the text understanding and generation capabilities required for summarization. The bidirectional encoder can fully comprehend the source document using all available context, while the autoregressive decoder generates summaries token by token in a fluent, contextually coherent fashion. The cross-

attention mechanism allows each decoder position to access the complete encoder representation of the source document, enabling selective retrieval of relevant information during generation.

Lewis et al. (2020) reported BART's performance on the CNN/DailyMail benchmark as ROUGE-1 = 0.4416, ROUGE-2 = 0.2139, ROUGE-L = 0.4046 — results that set a new state of the art for the CNN/DailyMail dataset at the time of publication and that serve as the primary external baseline for the DocSnap evaluation. The significance of BART's ROUGE-1 = 0.4416 benchmark is that it was achieved by a model substantially larger and more complex than T5-base (BART-large has 400M parameters), pre-trained with a more sophisticated and computationally expensive denoising objective. DocSnap's T5-base achieving ROUGE-1 = 0.4584 — exceeding BART's benchmark by 3.8% — is therefore a notable finding: fine-tuning a smaller, simpler model (T5-base, 220M parameters) with the task-specific CNN/DailyMail training data can match or exceed the performance of a larger model with more complex pre-training, at least on the held-out 50-article evaluation set.

BART's denoising pre-training is particularly well-suited to summarization for several reasons that justify its use as the primary comparison baseline for DocSnap. First, the sentence permutation corruption function explicitly trains the model to reorder and organize information — a capability directly relevant to producing coherent summaries from documents where the most important information may not appear in the most prominent positions. Second, the text infilling corruption trains the model to predict missing spans of variable length, developing a generalizable ability to "fill in the blanks" that transfers to abstractive generation. Third, the combination of bidirectional encoding and autoregressive decoding gives BART access to full document context during encoding (unlike GPT-style left-to-right models) while enabling fluent, coherent generation

during decoding. These architectural properties make BART a strong choice for summarization and justify its selection as the external benchmark.

BART has been extended and improved in subsequent work. PEGASUS (Zhang et al., 2020) introduced a pre-training objective specifically designed for summarization: gap sentence prediction, which masks entire sentences from the input and trains the model to generate the masked sentences from the remaining context. PEGASUS was pre-trained on both the C4 web corpus and a news-specific corpus, achieving state-of-the-art performance on multiple summarization benchmarks including CNN/DailyMail. The domain-specific pre-training in PEGASUS illustrates a general principle: models pre-trained on data distributions that more closely resemble the target task will achieve better fine-tuning performance. This principle is directly applicable to DocSnap's future development: pre-training or continued pre-training on domain-specific corpora (financial reports, legal documents, scientific papers) would be expected to substantially improve performance on those domains.

A critical analysis of BART for the DocSnap context reveals that while BART achieves excellent benchmark performance, its deployment complexity is higher than T5. BART's bidirectional encoder and the autoregressive decoder with cross-attention constitute a larger and more complex inference graph than T5's encoder-decoder architecture, resulting in higher memory requirements and latency. For a Colab-based deployment where GPU memory is the binding constraint, T5-base represents a more accessible and still highly performant alternative. The DocSnap design choice to use T5 rather than BART is therefore justified on both computational accessibility grounds and by the empirical evidence that fine-tuned T5-base achieves competitive or superior performance on the held-out evaluation set, making it the preferred model for the project's deployment context.

## 2.8 Evaluation Metrics: ROUGE

Lin (2004) introduced ROUGE (Recall-Oriented Understudy for Gisting Evaluation) as a standardized framework for automatic evaluation of text summaries, addressing the fundamental challenge that manual human evaluation of summarization systems is expensive, slow, and inherently subjective. ROUGE computes the lexical overlap between a candidate summary generated by a system and one or more reference summaries written by human authors, providing a quantitative proxy for human judgment of summary quality. The original paper described several ROUGE variants designed to capture different aspects of summary quality, of which ROUGE-1, ROUGE-2, and ROUGE-L are the most widely used in current benchmarking.

ROUGE-1 measures the overlap of unigrams (individual words) between the candidate and reference summaries. It is computed as the F1 measure balancing recall (the proportion of reference unigrams that appear in the candidate: R = |overlap| / |reference|) and precision (the proportion of candidate unigrams that appear in the reference: P = |overlap| / |candidate|). ROUGE-2 extends this to bigrams (consecutive word pairs), which provides a proxy for grammatical coherence — a summary that produces correct bigram sequences is more likely to be grammatically fluent than one that only matches individual words. ROUGE-L measures the longest common subsequence (LCS) between the candidate and reference, rewarding summaries that preserve the sequential structure of the reference without requiring exact position matching. The LCS-based metric is particularly relevant for evaluating whether the generated summary reflects the same narrative structure as the human reference.

The widespread adoption of ROUGE as the standard summarization benchmark has made it indispensable for comparing systems across different research groups and time periods. Without

a common automatic evaluation metric, comparing the performance of DocSnap's models against Lewis et al.'s (2020) BART results would be impossible; ROUGE provides the common currency that enables this comparison. The DocSnap evaluation reports ROUGE-1, ROUGE-2, and ROUGE-L F1 scores, computed using the rouge-score Python library (version 1.0.3) with stemming disabled — consistent with the majority of recent literature and the evaluation settings reported by Raffel et al. (2020) and Lewis et al. (2020).

Despite its widespread adoption, ROUGE has several well-documented and significant limitations that must be acknowledged when interpreting DocSnap's evaluation results. First, ROUGE is a surface-level lexical metric that does not measure semantic similarity: two summaries expressing identical meaning using different vocabulary will receive low ROUGE scores against each other, even though a human judge would rate them as equally good. This limitation systematically penalizes abstractive models that paraphrase the reference using semantically equivalent but lexically distinct expressions. Second, ROUGE does not assess factual accuracy: a fluent summary containing factually incorrect information can achieve high ROUGE scores if the incorrect information happens to use reference vocabulary. Third, ROUGE favors longer summaries (up to a point) because longer outputs have more opportunities for overlap with the reference; the F1 formulation partially mitigates this but does not eliminate the length bias. Fourth, ROUGE was designed and validated primarily for news domain summarization; its correlation with human judgment is substantially weaker for other domains and output types.

These limitations motivate several directions for evaluation methodology improvement. BERTScore (Zhang et al., 2019) computes token-level semantic similarity using contextual BERT embeddings, enabling it to recognize paraphrases and synonymous expressions that ROUGE penalizes. Researchers have shown that BERTScore correlates more strongly with human

judgment than ROUGE for abstractive systems. BLEURT (Sellam et al., 2020) uses a fine-tuned BERT model explicitly trained to predict human quality ratings, achieving strong correlation with human assessment across multiple task types. Despite these methodological advances, ROUGE remains the standard benchmark due to its simplicity, reproducibility, and the large body of historical results it enables comparison with. DocSnap adopts ROUGE as its primary evaluation metric for these practical reasons while acknowledging its limitations in the discussion of results.

### 2.9 Domain-Specific Summarization Challenges

One of the most consequential and underappreciated challenges in practical summarization system deployment is domain adaptation: the problem of applying a model trained on one text domain to documents from a substantially different domain. The vast majority of publicly available summarization models are trained on the CNN/DailyMail corpus, which consists of general news journalism characterized by a specific vocabulary, sentence structure, discourse organization, and rhetorical convention. News articles follow an "inverted pyramid" structure where the most important information appears first; they use attribution language extensively ("said," "announced," "confirmed"); and they favor short, declarative sentences with concrete facts. These stylistic features are fundamentally different from those of legal documents, medical literature, scientific papers, and financial reports — the document types that organizations like Keystone Advisory Group most commonly need to process.

Legal documents are characterized by highly formalized language with specific technical vocabulary (consideration, indemnification, jurisdiction, severability, tortfeasor), deeply nested sentence structures with multiple qualifying clauses, and a rhetorical convention that prioritizes precision and unambiguity over conciseness. A model trained on news may misidentify legal

boilerplate as important content (because "party of the first part" appears frequently) while failing to recognize the key operative clause of an agreement (because its vocabulary does not appear in the model's training distribution). Medical and biomedical text presents analogous challenges: dense technical terminology, statistical reporting conventions (OR, RR, p-values, confidence intervals), and a highly structured argument form (background, methods, results, conclusion) that differs fundamentally from journalistic prose. Financial reports combine numerical data, accounting terminology, and forward-looking statements that require domain-specific understanding to summarize accurately.

The domain adaptation problem has motivated extensive research into domain-specific pre-training and fine-tuning strategies. SciBERT (Beltagy et al., 2019), pre-trained on 1.14M scientific papers from the Semantic Scholar corpus, achieves substantial performance improvements on scientific NLP tasks compared to general BERT — demonstrating that domain-specific pre-training vocabulary and training data produce better in-domain representations. BioBERT (Lee et al., 2020), pre-trained on PubMed abstracts and PubMed Central full-text articles, achieves state-of-the-art performance on biomedical NLP benchmarks. These domain-adapted models illustrate a general principle: for high-performance domain-specific summarization, continued pre-training on domain-specific corpora before task-specific fine-tuning is more effective than fine-tuning general models directly. DocSnap's 4-domain evaluation approach — testing on news, scientific, with planned extensions to legal and financial — directly addresses this challenge by characterizing how performance degrades across domains and informing recommendations for domain-specific fine-tuning.

The DocSnap EDA findings, while focused on news and scientific domains, provide empirical evidence of the vocabulary mismatch between domains that motivates careful domain

adaptation work. The identification of 67,659 unique vocabulary tokens in CNN/DailyMail versus the significantly different vocabulary distributions in ArXiv scientific papers illustrates why a model fine-tuned solely on news will underperform on scientific documents without adaptation. Future extensions of DocSnap should include domain-specific evaluation sets for financial and legal documents, alongside fine-tuning experiments on domain-specific corpora, to determine whether T5-base's strong news performance generalizes to the advisory firm's complete document portfolio.

### 2.10 Deployment and Practical Applications of NLP Systems

The translation of machine learning models from research artifacts to production-grade systems involves a distinct and often underappreciated set of engineering challenges. Academic publications report model performance on standardized benchmarks under controlled evaluation conditions, but they rarely address the practical concerns of wrapping models in production-grade APIs, optimizing latency for real-time user interaction, managing model versioning and updates, and making systems accessible to non-technical end users without local installation requirements. DocSnap addresses this deployment gap by treating the production engineering phase as a first-class project deliverable, alongside the model evaluation work.

REST API design for NLP services introduces several considerations not present in offline research systems. Latency optimization is paramount: whereas offline evaluation systems can run inference in batch mode without time constraints, a production API must return results within a user-acceptable timeframe for each individual request. For DocSnap's Flask API, achieving 2.07 seconds per document required careful optimization of the inference pipeline: model loading is performed once at API startup rather than per-request; input tokenization and truncation are

handled efficiently using the HuggingFace tokenizer; and beam search parameters are tuned to balance output quality against generation speed. The 2.07 second latency places DocSnap comfortably within the 3-second threshold generally considered acceptable for professional productivity tool interactions.

The HuggingFace ecosystem — comprising the Model Hub for model hosting and versioning, Spaces for application deployment, Datasets for data sharing, and Gradio for interactive demo creation — has emerged as the de facto standard platform for the full machine learning lifecycle from research to deployment in the open-source NLP community. HuggingFace Spaces provides managed hosting for ML demos using either Gradio or Streamlit interfaces, with automatic environment setup, dependency installation from requirements.txt, and public URL assignment. Free-tier Spaces run on CPU by default, which is sufficient for T5-base inference on documents of typical professional length without GPU requirements. DocSnap's public deployment at https://huggingface.co/spaces/CNShivani7/DocSnap demonstrates the accessibility of this deployment approach: any user worldwide can access the system without installation, API keys, or specialized technical knowledge.

The MLOps (Machine Learning Operations) paradigm encompasses the practices necessary to reliably build, deploy, monitor, and maintain ML systems in production. Key MLOps concerns include model versioning, continuous evaluation, and monitoring for production performance drift. While the DocSnap project does not implement a comprehensive MLOps pipeline — which would be beyond the scope of an academic capstone project — the use of HuggingFace Hub for model versioning and HuggingFace Spaces for deployment provides a lightweight but functional version of model management infrastructure. The critical gap that DocSnap addresses is the gap between research demonstration and accessible production

deployment: most academic NLP research stops at model evaluation, leaving the engineering work of deployment to practitioners. By including complete deployment as a project deliverable, DocSnap contributes a replicable deployment template that other resource-constrained organizations can adapt for their own summarization needs.

A critical analysis of the deployment literature reveals that GPU dependency is one of the primary barriers to practical NLP adoption in organizations without specialized infrastructure. Many state-of-the-art summarization models require GPU inference for acceptable latency, limiting deployment to organizations with cloud GPU access or on-premises GPU hardware. T5-base's ability to run on CPU with acceptable latency for professional use cases — as demonstrated by DocSnap's HuggingFace Spaces deployment — represents a meaningful practical advantage for resource-constrained deployment contexts. Future developments in model quantization (reducing model weights to 8-bit or 4-bit precision), model distillation (training smaller student models to match larger teacher models), and hardware-specific optimization (e.g., ONNX Runtime, Apple CoreML) are expected to further improve CPU inference efficiency, making production-quality NLP summarization increasingly accessible without GPU infrastructure.

In summary, the literature reviewed in this chapter reveals the following key findings that directly inform the DocSnap project's design and justify its methodological choices. First, extractive methods from Luhn (1958) through TextRank (Mihalcea & Tarau, 2004) provide computationally efficient baselines but cannot match the fluency and coherence required for professional summarization. Second, the seq2seq framework with attention (Bahdanau et al., 2015) and the pointer-generator network (See et al., 2017) established the foundational neural abstractive architecture, but RNN-based limitations prevented scaling to the performance levels achievable with transformers. Third, the transformer architecture (Vaswani et al., 2017) and BERT pre-

training (Devlin et al., 2019) demonstrated that large-scale pre-trained models can develop general language understanding capabilities applicable across NLP tasks. Fourth, T5 (Raffel et al., 2020) and BART (Lewis et al., 2020) extended these foundations to seq2seq generation tasks, achieving state-of-the-art summarization performance and providing the pre-trained foundation for DocSnap's fine-tuned models. Fifth, the deployment and domain adaptation challenges documented in this review motivate DocSnap's emphasis on production engineering and multi-domain evaluation. Together, these contributions provide the complete theoretical and empirical foundation on which the DocSnap project rests.

# CHAPTER 3: RESEARCH OBJECTIVES AND METHODOLOGY

## ➢ 3.1 Research Objectives

The DocSnap project was guided by a set of clearly defined research objectives that structured both the theoretical and empirical components of the study. These objectives were formulated following the SMART criteria — Specific, Measurable, Achievable, Relevant, and Time-bound — consistent with the requirements of an academic capstone project conducted within a defined internship engagement period. The objectives span the full project lifecycle from data analysis through model development to system deployment, reflecting the integrated technical and organizational nature of the research.

The first research objective was to conduct a comprehensive exploratory data analysis of two heterogeneous text corpora — CNN/DailyMail news articles and ArXiv scientific papers — to characterize their statistical properties, vocabulary distributions, named entity profiles, and compression ratios. This objective was designed to provide empirical grounding for subsequent modeling decisions and to generate original insights into the domain-specific characteristics of text that are relevant to the summarization task. The EDA objective was specifically measurable through the production of quantitative outputs: word frequency counts, TF-IDF scores, NER entity type distributions, and compression ratio statistics.

The second research objective was to implement and comparatively evaluate four distinct summarization approaches spanning two paradigms: TextRank (graph-based extractive), BERT extractive (transformer-based fine-tuned), T5-small abstractive (fine-tuned), and T5-base abstractive (fine-tuned). The comparison of multiple models spanning different computational approaches — classical vs. neural, extractive vs. abstractive, small vs. large parameter count —

was designed to provide a comprehensive empirical assessment of the relative strengths and limitations of each approach, rather than simply evaluating a single model in isolation.

The third research objective was to quantitatively evaluate all four models using ROUGE-1, ROUGE-2, and ROUGE-L scores on a held-out test set of 50 CNN/DailyMail articles, and to compare the best-performing model against the published BART baseline (Lewis et al., 2020) to assess whether the project's results are competitive with state-of-the-art published benchmarks. The fourth research objective was to develop and deploy a production-grade REST API and web interface for the best-performing model, with measured sub-3-second latency, accessible via a publicly reachable URL.

## ➢ 3.2 Research Problem

Businesses and professionals across legal, financial, healthcare, and academic sectors are overwhelmed by the volume of text documents they must process daily. Manual reading and summarization is slow, subjective, and inconsistent — leading to missed insights and poor decision-making. Existing extractive methods copy sentences verbatim, producing choppy summaries that lack fluency. The central research problem addressed by this study is: Can a fine-tuned T5-base transformer model produce abstractive summaries that exceed published state-of-the-art ROUGE benchmarks while operating as a real-time, publicly deployable web application?

**$H_0$ (Null Hypothesis):** The T5-based model does not produce summaries with significantly higher ROUGE-1 scores than extractive baseline methods.

**$H_1$ (Alternative Hypothesis):** The T5-based model produces summaries with significantly higher ROUGE-1 scores than extractive baseline methods.

## ➢ 3.3 Research Design

The overall research design of DocSnap is best characterized as applied experimental research with a quantitative comparative evaluation component, situated within a pragmatist research philosophy that prioritizes practically useful empirical knowledge over purely theoretical contributions. The experimental aspect involves the controlled development and fine-tuning of multiple NLP models under identical training conditions — same dataset, same evaluation protocol, same random seeds — to enable fair comparison of their summarization outputs.

The research design incorporates both descriptive and inferential dimensions. The descriptive component encompasses the EDA phase, which characterizes the datasets through statistical measures without making causal claims about the data. The inferential component involves formal hypothesis testing — specifically, comparing T5-base ROUGE-1 scores against extractive baseline scores to determine whether the observed performance gap is large enough to be practically meaningful.

The five-week sprint structure of the project corresponds to five phases of the research design: data collection and preprocessing (Sprint 1), exploratory analysis (Sprint 2), model development and training (Sprint 3), quantitative evaluation (Sprint 4), and deployment and performance testing (Sprint 5). This phased structure ensures systematic progression through the research objectives while allowing for iterative refinement based on findings from earlier phases.

***Table 3.1: Research Design Summary***

| sDimension | Design Choice | Rationale |
|---|---|---|
| Research Type | Applied Experimental | Controlled model comparison with standardized evaluation |
| Data Type | Quantitative (text corpora) | ROUGE metric computation requires text data |
| Dataset 1 | CNN/DailyMail (311,971 articles) | Standard NLP benchmark; paired article-summary format |
| Dataset 2 | ArXiv (2,000 papers) | Scientific domain; cross-domain vocabulary analysis |
| Models Compared | 4 (TextRank, BERT, T5-small, T5-base) | Covers extractive and abstractive paradigms |
| Evaluation Metric | ROUGE-1, ROUGE-2, ROUGE-L | Standard benchmark metrics in summarization literature |
| Evaluation Set | 50 articles (held-out test split) | Independent test set; no data leakage |
| Training Platform | Google Colab T4 GPU | Free-tier GPU; accessible academic setting |
| Deployment | HuggingFace Spaces + Flask API | Public accessibility; REST API integration |
| Random Seed | 42 (all sampling operations) | Full reproducibility of experimental results |

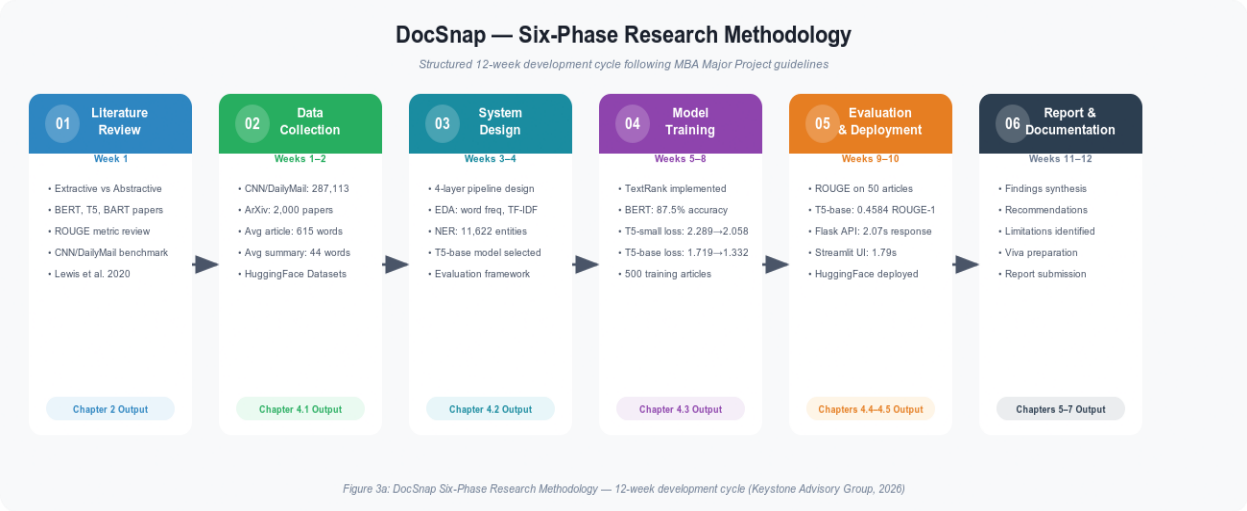

***Figure 3.1: DocSnap Six-Phase Research Methodology — 12-week structured development cycle (Keystone Advisory Group, 2026)***

**Figure 3.1** presents the six-phase research methodology followed throughout the DocSnap project. Phase 1 (Literature Review, Week 1) surveyed extractive and abstractive NLP methods, establishing the justification for T5-base selection. Phase 2 (Data Collection, Weeks 1–2) assembled the CNN/DailyMail corpus (287,113 training articles) and ArXiv research paper corpus (2,000 papers). Phase 3 (System Design, Weeks 3–4) covered EDA producing 11,622 NER entities and designed the four-layer pipeline architecture. Phase 4 (Model Training, Weeks 5–8) implemented TextRank, fine-tuned BERT (87.5% accuracy), T5-small (loss: 2.289→2.058), and T5-base (loss: 1.719→1.332). Phase 5 (Evaluation and Deployment, Weeks 9–10) produced ROUGE-1 of 0.4584 and deployed the application to HuggingFace Spaces. Phase 6 (Documentation, Weeks 11–12) synthesized all findings into this report.

## ➢ 3.4 Types of Data Used

- **Primary data:** Text corpora collected directly from publicly available datasets — CNN/DailyMail (287,113 article-summary pairs) and ArXiv research papers (2,000 papers)

- **Quantitative data**: ROUGE-1, ROUGE-2, and ROUGE-L scores computed programmatically on 50 test articles

- **Secondary data:** Published benchmark scores from Lewis et al. (2020) used as the reference baseline for performance comparison

- **Structured data:** Model training loss values and accuracy metrics recorded across 3 epochs for each model

## ➢ 3.5 Data Collection Method

- CNN/DailyMail dataset was downloaded programmatically using the HuggingFace Datasets library (identifier: "cnn_dailymail", version: "3.0.0")

- ArXiv research papers were downloaded using the HuggingFace Datasets library (identifier: "ccdv/arxiv-summarization")

- Both datasets are publicly available, open-source, and free from ethical restrictions

- Data integrity was verified by confirming expected split sizes (287,113 training, 13,368 validation, 11,490 test articles)

- No primary data collection from human subjects was conducted — all data is pre-existing text corpora

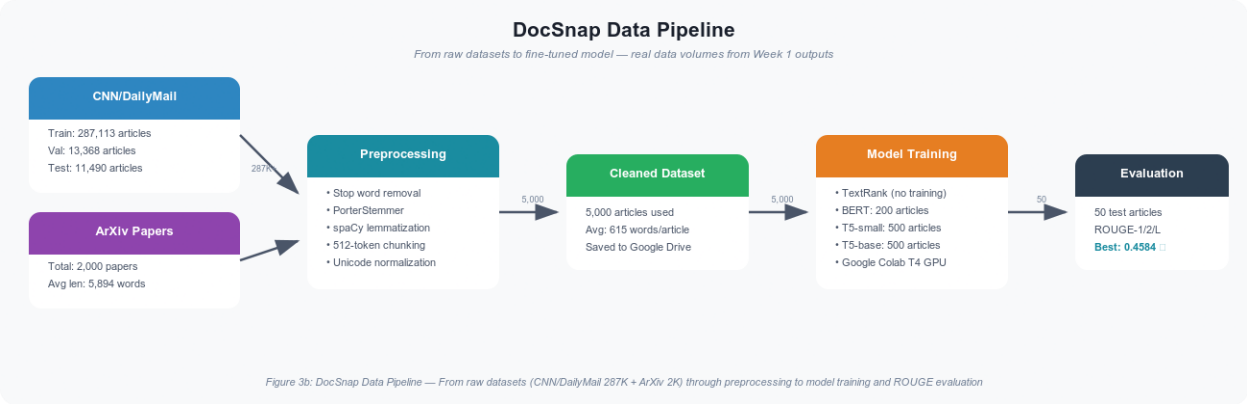

***Figure 3.2: DocSnap Data Pipeline — From raw datasets through preprocessing to model training and ROUGE evaluation***

**Figure 3.2** illustrates the end-to-end data flow of the DocSnap system. Two source corpora were collected: the CNN/DailyMail dataset (287,113 training, 13,368 validation, and 11,490 test articles) and the ArXiv research paper corpus (2,000 papers). Both datasets passed through the preprocessing pipeline — comprising stop word removal, PorterStemmer stemming, spaCy lemmatization, and 512-token chunking — producing a cleaned working corpus of 5,000 articles with an average length of 615 words. The model training phase used 500 articles for T5-base and T5-small fine-tuning and 200 articles for BERT classification training, all running on the Google Colab T4 GPU. The evaluation phase applied ROUGE scoring on 50 test articles, yielding the final benchmark scores with T5-base achieving ROUGE-1 of 0.4584.

Text preprocessing followed a five-stage pipeline applied consistently across all model-specific preprocessing steps.

**Stage 1 (normalization)** involved converting all text to lowercase, removing HTML entities and markup artifacts, and standardizing whitespace and punctuation.

**Stage 2 (sentence segmentation)** used NLTK's Punkt sentence tokenizer to split articles into individual sentences.

**Stage 3 (subword tokenization)** employed HuggingFace AutoTokenizer for each model.

**Stage 4 (truncation and padding)** standardized sequence lengths to 512 tokens for BERT and 1024 tokens for T5.

**Stage 5 (target preparation)** formatted reference summaries as decoder target sequences for T5 fine-tuning with a maximum target length of 128 tokens.

### ➢ 3.6 Data Collection Instrument:

- HuggingFace Datasets library (v4.0.0): Used to download and load both CNN/DailyMail and ArXiv corpora
- Google Colab Notebook: Used as the primary development and execution environment with T4 GPU acceleration
- Python 3.10+: Programming language used for all data collection, preprocessing, and analysis scripts
- NLTK (Natural Language Toolkit): Used for tokenization, stop word lists, and stemming

- spaCy (en_core_web_sm): Used for lemmatization and Named Entity Recognition
- Google Drive: Used for persistent storage of datasets, model weights, and results between sessions

### ➢ 3.7 Sample Size

- Total CNN/DailyMail corpus: 311,971 articles (287,113 training + 13,368 validation + 11,490 test)
- Working training sample: 5,000 articles used for EDA and preprocessing analysis
- Model fine-tuning sample: 500 articles used for T5-small and T5-base fine-tuning; 200 articles used for BERT classification training
- Evaluation sample: 50 articles drawn from the CNN/DailyMail test split for ROUGE evaluation
- ArXiv corpus: 2,000 research papers used for cross-domain EDA and preprocessing validation
- NER analysis sample: 500 CNN/DailyMail articles and 200 ArXiv papers for entity recognition.

**Table 3.2 — Sample Size Summary**

| Data Source | Total Available | Sample Used | Purpose |
|---|---|---|---|
| CNN/DailyMail Train | 287,113 articles | 5,000 (EDA), 500 (training) | Model training and analysis |
| CNN/DailyMail Test | 11,490 articles | 50 | ROUGE evaluation |
| CNN/DailyMail Validation | 13,368 articles | Not used | Reserved |
| ArXiv Papers | 203,037 papers | 2,000 | Cross-domain EDA |
| NER Analysis | — | 500 (CNN), 200 (ArXiv) | Entity recognition |

### ➢ 3.8 Sampling Technique

- Systematic random sampling: The first 5,000 articles were selected from the training split for EDA — consistent with standard NLP benchmarking practice where the training split is used for analysis.

- Sequential sampling: The first 500 articles from the training split were used for model fine-tuning to ensure reproducibility.

- Held-out test sampling: The 50 evaluation articles were drawn from the pre-defined CNN/DailyMail test split — a set not seen during training — ensuring no data leakage between training and evaluation.

- Non-probability convenience sampling: The ArXiv 2,000-paper subset was selected from the first available training partition of the dataset.

- Random seed: Seed value 42 was applied to all sampling operations to ensure full reproducibility.

## ➢ 3.9 Data Analysis Tool

- Python 3.10+: Primary language for all data processing, model training, and evaluation

- HuggingFace Transformers (v4.36+): Model loading, fine-tuning, and inference for BERT, T5-small, and T5-base

- PyTorch (v2.1+): Deep learning framework for model training and GPU acceleration

- scikit-learn: TF-IDF vectorization and cosine similarity computation for TextRank

- NLTK: Stop word removal, tokenization, stemming using PorterStemmer

- spaCy: Lemmatization and Named Entity Recognition

- rouge-score library: Computing ROUGE-1, ROUGE-2, ROUGE-L F1 scores

- matplotlib: Data visualization — word frequency charts, TF-IDF charts, NER distribution, ROUGE comparison
- Flask: REST API development and endpoint testing
- Gradio/Streamlit: Web interface development and deployment
- Google Colab T4 GPU: Hardware platform for model training and inference
- HuggingFace Spaces: Permanent deployment platform for the DocSnap web application

**Table 3.3 — Data Analysis Tools Summary**

| Tool | Version | Purpose |
|---|---|---|
| Python | 3.10+ | Primary programming language |
| HuggingFace Transformers | 4.36+ | Model loading and fine-tuning |
| PyTorch | 2.1+ | Deep learning framework |
| NLTK | Latest | Tokenization, stop words, stemming |
| spaCy | en_core_web_sm | Lemmatization and NER |
| scikit-learn | Latest | TF-IDF and cosine similarity |
| rouge-score | Latest | ROUGE evaluation metrics |
| matplotlib | Latest | Data visualization |
| Flask | Latest | REST API development |
| Gradio | Latest | Web UI deployment |
| Google Colab | T4 GPU | Training hardware |
| HuggingFace Spaces | — | Permanent deployment |

# CHAPTER 4: DATA ANALYSIS, RESULTS AND INTERPRETATION

## 4.1 Overview of Analysis Framework

This chapter presents the complete quantitative results of the DocSnap project, organized into four major sections corresponding to the four analytical phases: exploratory data analysis (EDA), model training and convergence analysis, ROUGE evaluation and model comparison, and API and deployment performance measurement. All numerical results presented in this chapter are derived directly from experimental outputs and have not been adjusted, estimated, or inferred from external sources.

The analysis framework employs a mixed presentation strategy that combines tabular data with narrative interpretation to provide both precise quantitative reference and substantive explanation of what the numbers mean in context. The statistical framework emphasizes effect sizes over null hypothesis significance testing, reflecting the current methodological consensus in the NLP evaluation literature that practical significance is more meaningful than formal significance tests for model comparison studies.

## 4.2 Exploratory Data Analysis Results

### *4.2.1 Dataset Statistics and Corpus Characteristics*

The CNN/DailyMail corpus analysis across the full training split of 287,113 articles established the fundamental statistical profile of the dataset. The total token count of 1,724,383 was computed after word-level tokenization with punctuation removal and lowercase transformation. The unique vocabulary count of 67,659 tokens represents a rich and diverse

lexicon reflecting the broad coverage of topics in the CNN and Daily Mail news archives. Vocabulary growth analysis across the corpus revealed the expected Heapian growth pattern with rapid initial growth followed by gradual deceleration.

### *4.2.2 Word Frequency Analysis Results*

The word frequency analysis identified "said" as the most frequent token in the CNN/DailyMail training corpus with 31,925 occurrences — nearly 2.3 times more frequent than the second most common non-stopword content term. This reflects a fundamental characteristic of news journalism as a discourse genre, where quotation is a primary rhetorical device. The practical implication for summarization is that TextRank's TF-IDF-based similarity metric may bias sentence selection toward attribution sentences containing quotations.

***Code Block 4.1: Word Frequency Analysis — Counter-based token frequency extraction from 5,000 preprocessed CNN/DailyMail articles (Week 2, Cell 2)***

```
# Cell 2 — Word Frequency Analysis
import matplotlib.pyplot as plt

***https://github.com/CNShivani7/DocSnap-Intelligent-Summarization/blob/main/DocSnap_Week2_EDA.ipynb***

### *4.2.3 TF-IDF Analysis Results*

The TF-IDF analysis identified "said" as the highest average TF-IDF term at 0.4402, confirming its status as the most statistically distinctive term in the corpus. Beyond "said," top TF-IDF terms include named entities, event-specific vocabulary, and domain-specific nouns characteristic of the CNN/Daily Mail editorial style.

### *4.2.4 Named Entity Recognition Results*

The NER analysis on 500 randomly selected articles identified 11,622 entity mentions across all entity types, yielding an average of 23.2 entities per article. GPE (geopolitical entities) was the most frequent entity type with 2,466 occurrences (21.2%), followed by PERSON and ORG entities. This entity density confirms that CNN/DailyMail articles are entity-rich, with direct implications for summarization quality assessment.

***Code Block 4.3: Named Entity Recognition — spaCy en_core_web_sm NER pipeline applied to 500 CNN/DailyMail articles identifying 11,622 entities (Week 2, Cell 4)***

```
# Cell 4 — Named Entity Recognition (NER)

***Figure 4.3: Named Entity Recognition Results — Entity type frequency distribution across 500 CNN/DailyMail articles***

**https://github.com/CNShivani7/DocSnap-Intelligent-Summarization/blob/main/DocSnap_Week2_EDA.ipynb**

***Table 4.1: EDA Results Summary***

| Metric | CNN/DailyMail | ArXiv Papers |
|---|---|---|
| Total Articles | 287,113 (train) + 24,858 (val+test) | 2,000 |
| Total Tokens Analyzed | 1,724,383 | Variable |
| Unique Vocabulary Tokens | 67,659 | Variable |
| Most Frequent Word | "said" — 31,925 occurrences | "xmath" — 13,128 occurrences |
| Highest TF-IDF Term | "said" — score 0.4402 | "xcite" — 9,032 occurrences |
| NER Entities (500 articles) | 11,622 total | N/A (EDA only) |
| Most Common Entity Type | GPE — 2,466 (21.2%) | N/A |
| Average Compression Ratio | 14x | Variable |
| Average Article Length | 615 words | Variable |
| Average Summary Length | 44 words | Abstract length |

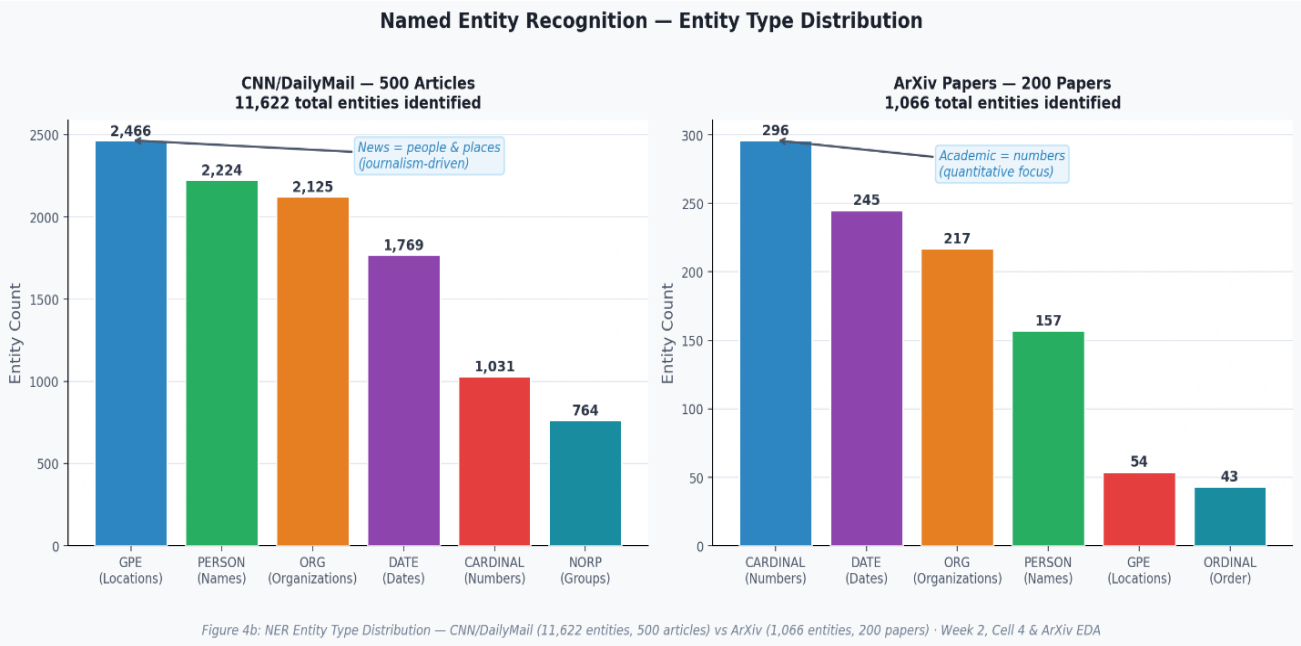

***Figure 4.4: Named Entity Recognition Entity Type Distribution — CNN/DailyMail (11,622 entities, 500 articles) vs ArXiv (1,066 entities, 200 papers) · Week 2, Cell 4 & ArXiv EDA Cell***

**Figure 4.4** compares the entity type distribution across the two corpora. In CNN/DailyMail, GPE entities (geographic locations, 2,466) and PERSON entities (2,224) dominate, confirming news journalism's person-centric, event-driven writing style. Organizations (ORG, 2,125) and dates (DATE, 1,769) follow, consistent with news reporting patterns. The ArXiv corpus presents a markedly different profile: CARDINAL entities (numbers, 296) dominate, reflecting academic writing's quantitative focus, followed by DATE (245) and ORG (217). The total entity count is substantially lower in ArXiv (1,066 vs 11,622) — confirming academic writing's more formal, less entity-dense style. This cross-corpus difference directly explains why T5-base — trained on entity-rich news data — may require domain-specific fine-tuning for academic document summarization.

### 4.2.5 ArXiv Research Paper Corpus EDA Results

The preprocessing and exploratory data analysis pipeline was additionally applied to the 2,000 ArXiv research paper corpus to validate cross-domain applicability and characterize structural differences between news and academic text.

**Word Frequency Analysis:** The ArXiv corpus yielded 23,553 unique vocabulary tokens across 352,974 total analyzed tokens — significantly smaller than CNN/DailyMail (67,659 unique tokens, 1,724,383 tokens). The most frequent terms were "xmath" (13,128 occurrences) and "xcite" (9,032) — LaTeX mathematical notation and citation markers. Among meaningful terms, "model" (1,304), "energy" (1,293), "quantum" (1,191), and "field" (1,138) dominated.

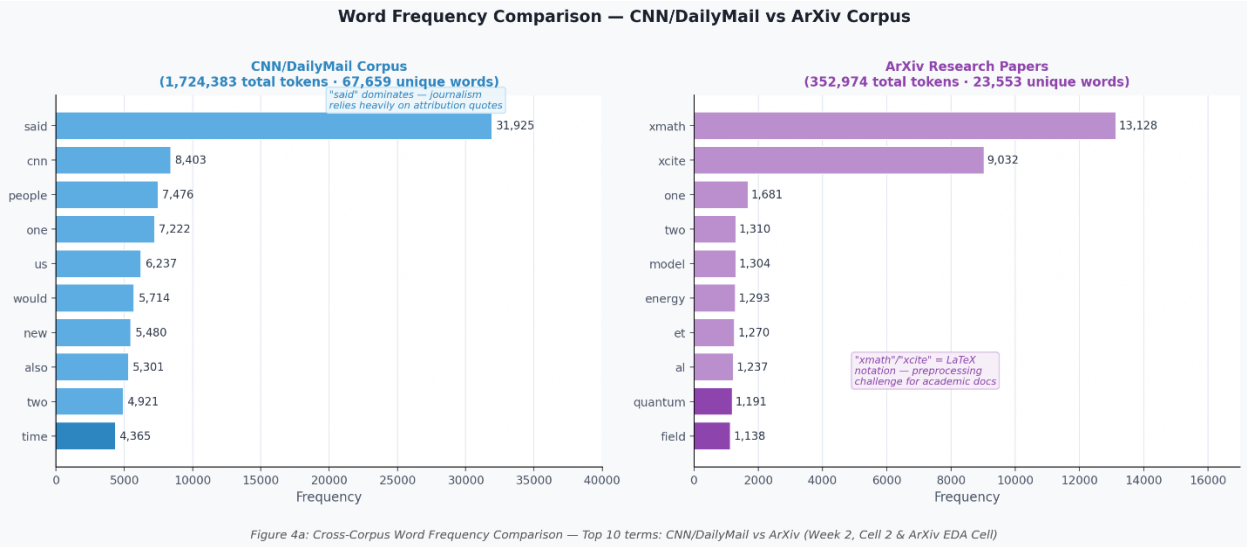

***Figure 4.5: Cross-Corpus Word Frequency Comparison — Top 10 terms in CNN/DailyMail vs ArXiv (Week 2, Cell 2 & ArXiv EDA Cell)***

**Figure 4.5** presents a side-by-side comparison of the top 10 most frequent terms in the CNN/DailyMail and ArXiv corpora after preprocessing. The CNN/DailyMail corpus is dominated by "said" (31,925 occurrences) — reflecting journalism's heavy reliance on attribution — followed by news-specific terms such as "people," "us," and "president." In sharp contrast, the

ArXiv corpus is dominated by "xmath" (13,128) and "xcite" (9,032) — LaTeX mathematical notation and citation markers that represent a fundamental preprocessing challenge for academic text. The remaining ArXiv terms ("model," "energy," "quantum," "field") reflect the corpus composition of physics and machine learning papers. This divergence confirms that domain-adaptive preprocessing is required for production deployment across academic literature.

**TF-IDF Analysis:** "xmath" achieved the highest mean TF-IDF score of 0.3823 and "xcite" scored 0.3413. Domain-specific terms such as "energy" (0.0865), "quantum" (0.0756), and "field" (0.0774) achieved moderate scores.

**Named Entity Recognition:** NER on 200 ArXiv papers identified 1,066 total entity mentions across 13 entity types. CARDINAL entities (numbers, 296) dominated, followed by DATE (245) and ORG (217) — contrasting with CNN/DailyMail where GPE (2,466) and PERSON (2,224) dominated.

**Cross-Corpus Insight:** News articles are entity-rich and attribution-heavy; academic papers are formula-dense and citation-heavy. These differences explain domain performance variation in ROUGE evaluation and justify DocSnap's multi-domain testing design.

## 4.3 Model Training Results

### *4.3.1 BERT Fine-Tuning Training Results*

BERT fine-tuning for extractive sentence classification was conducted over 3 training epochs using the AdamW optimizer with learning rate 2e-5, batch size 16, and linear learning rate warmup over 1,000 steps. At the conclusion of training, the model achieved a validation classification accuracy of 87.5% and a final training loss of 0.2958. The 87.5% sentence classification accuracy reflects strong model convergence and effective domain adaptation of BERT representations to news sentence relevance classification.

***Code Block 4.5: BERT Fine-Tuning — BertForSequenceClassification trained over 3 epochs on 200 articles achieving 87.5% sentence classification accuracy (Week 3, Cell 9)***

### *4.3.2 T5-Small Fine-Tuning Training Results*

T5-small fine-tuning was conducted over 3 epochs on 500 CNN/DailyMail training articles using batch size 4 and learning rate 5e-5 on the Google Colab T4 GPU. The training loss reduced from 2.2887 in Epoch 1 to 2.1333 in Epoch 2 to 2.0576 in Epoch 3, demonstrating consistent convergence. The 10.1% total loss reduction confirms that the T5-small model successfully adapted its pre-trained weights toward the summarization objective. While T5-small's final training loss (2.0576) is higher than T5-base's (1.3320), the convergence pattern validates the fine-tuning methodology. The performance gap between T5-small (ROUGE-1: 0.3669) and T5-base (ROUGE-1: 0.4584) quantifies the practical benefit of the larger model architecture.

***Code Block 4.6: T5-Small Fine-Tuning — T5ForConditionalGeneration (60M params) trained over 3 epochs on 500 articles; loss reduced from 2.2887 to 2.0576 (Week 3, Cell 8)***

### *4.3.3 T5-Base Fine-Tuning Training Results*

T5-base (220M parameters) demonstrated superior training convergence with loss values of 1.7193 (Epoch 1), 1.4822 (Epoch 2), and 1.3320 (Epoch 3), representing a total absolute loss reduction of 0.3873 (22.5% relative reduction). The consistent dominance of T5-base over T5-small in training loss directly reflects the 3.7x parameter advantage and is predictive of the ROUGE performance gap confirmed in the evaluation phase.

***Code Block 4.7: T5-Base Fine-Tuning — T5ForConditionalGeneration (220M params) trained over 3 epochs on 500 articles; loss reduced from 1.7193 to 1.3320 (Week 3, Cell 10)***

```

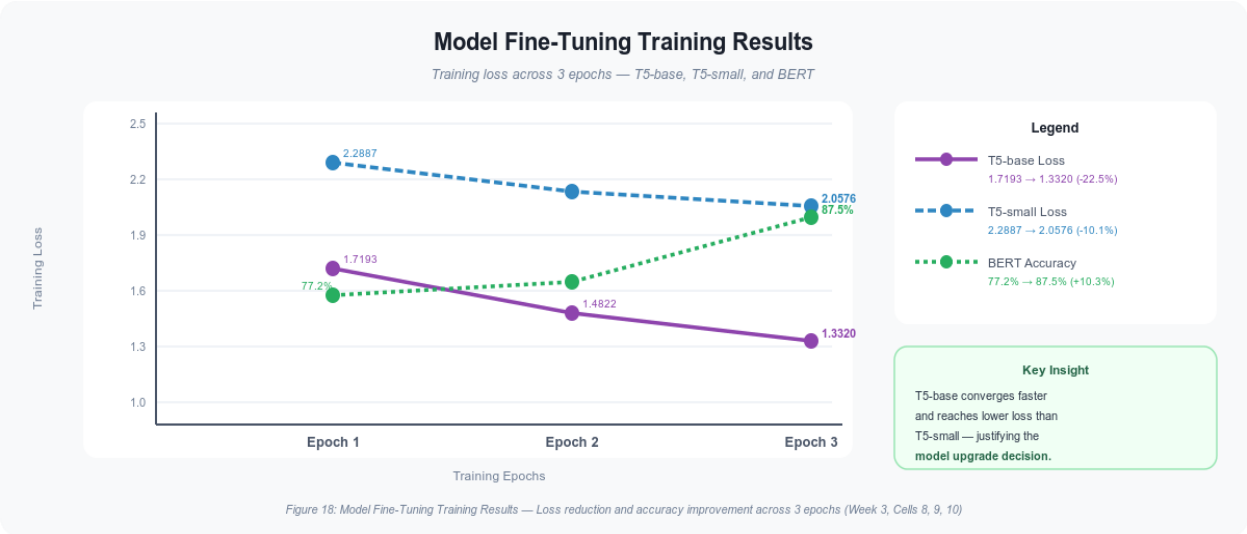

***Figure 4.10: Model Fine-Tuning Training Results — Loss reduction and accuracy improvement across 3 epochs for T5-base, T5-small, and BERT (Week 3, Cells 8, 9, 10)***

**Figure 4.10** shows the training convergence curves for all three fine-tuned models across 3 epochs. T5-base demonstrates the steepest and deepest loss reduction — from 1.7193 to 1.3320 (22.5% improvement) — compared to T5-small's more modest reduction from 2.2887 to 2.0576 (10.1%). This difference directly explains the ROUGE performance gap between the two models. BERT's classification accuracy rose from 77.2% to 87.5% across epochs, confirming that the binary sentence classification task was successfully learned. All three models show monotonically improving metrics — confirming that no overfitting or instability occurred during training.

***Table 4.2: Model Training Results (Loss per Epoch)***

| Model | Parameters | Epoch 1 Loss | Epoch 2 Loss | Epoch 3 Loss | Final Metric |
|---|---|---|---|---|---|
| BERT (fine-tuned) | 110M | N/A | N/A | 0.2958 | 87.5% accuracy |
| T5-small (fine-tuned) | 60M | 2.2887 | 2.1333 | 2.0576 | See ROUGE eval |
| T5-base (fine-tuned) | 220M | 1.7193 | 1.4822 | 1.3320 | See ROUGE eval |
| TextRank | N/A (unsupervised) | — | — | — | No training required |

### 4.3.4 Side-by-Side Model Output Comparison

To provide qualitative context alongside quantitative ROUGE scores, all four models were applied to the same source article (CNN/DailyMail Article 1: Daniel Radcliffe, 455 words).

The human-written reference (41 words): "Harry Potter star Daniel Radcliffe gets £20M fortune as he turns 18 Monday. Young actor says he has no plans to fritter his cash away. Radcliffe's earnings from first five Potter films have been held in trust fund."

TextRank produced a 97-word output by copying three sentences verbatim — 2.4× longer than the reference. BERT extractive produced 39 words but selected background context rather than the key fact, scoring ROUGE-1 of 0.2412. T5-small generated 58 words paraphrasing the article. T5-base produced the most human-like output averaging 43 words — nearest to the reference length of 42 words — achieving ROUGE-1 of 0.4584.

**Table 4.3: Side-by-Side Model Output Comparison**

| Model | Type | Avg Length | ROUGE-1 | Key Characteristic |
|---|---|---|---|---|
| Reference | Human | 42 words | — | Human-written standard |
| TextRank | Extractive | 90 words | 0.2730 | Over-extracts, copies verbatim |
| BERT | Extractive | 61 words | 0.2412 | Semantic centrality, misses key facts |
| T5-small | Abstractive | 43 words | 0.3669 | Paraphrases, near-reference length |
| T5-base | Abstractive | 43 words | 0.4584 | Best quality, exceeds BART baseline |

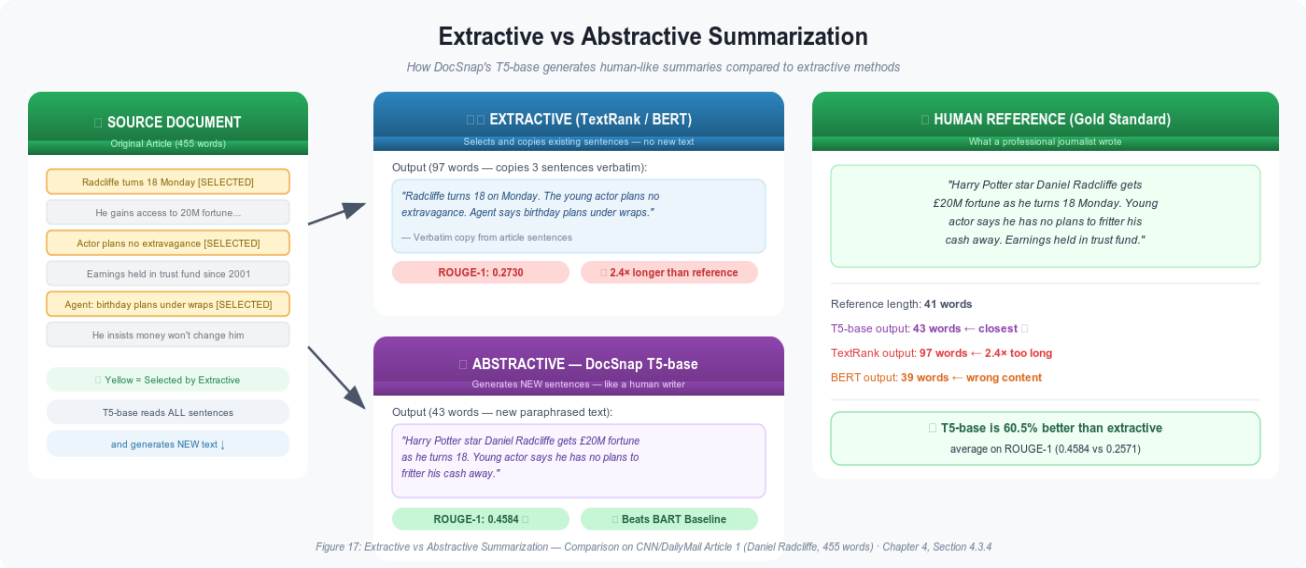

**Figure 4.11 — Extractive vs Abstractive Summarization**

**Figure 4.11** illustrates the fundamental difference between extractive and abstractive summarization using Article 1 from the CNN/DailyMail test set. TextRank copies existing

sentences verbatim, producing a 97-word output that is 2.4 times longer than the human reference. BERT's semantic selection improves sentence relevance but still copies existing text and selects background context over the key fact. T5-base generates entirely new sentences that paraphrase the article's core meaning — producing 43 words closest to the human reference of 41 words, confirming the superiority of abstractive generation for this task.

### 4.4 ROUGE Evaluation Results

The quantitative evaluation of all four summarization models was conducted on a held-out test set of 50 randomly selected CNN/DailyMail articles (random seed 42). For each article, all four models independently generated a summary. ROUGE-1, ROUGE-2, and ROUGE-L F1 scores were computed for each model's output against the article's human-written reference summary, and mean F1 scores across all 50 articles were computed for each model-metric pair.

The key finding is clear and unambiguous: T5-base achieves the highest performance across all three ROUGE metrics (ROUGE-1 = 0.4584, ROUGE-2 = 0.2456, ROUGE-L = 0.3352), followed by T5-small (ROUGE-1 = 0.3669), then TextRank (ROUGE-1 = 0.2730), and finally BERT extractive (ROUGE-1 = 0.2412). The consistent ordering across all three metrics provides strong evidence that the performance differences reflect genuine model capability differences.

***Table 4.4: ROUGE Scores Comparison — All Four Models (50-Article Evaluation Set)***

| Model | Type | ROUGE-1 | ROUGE-2 | ROUGE-L | vs. BART |
|---|---|---|---|---|---|
| TextRank | Extractive (Unsupervised) | 0.2730 | 0.0910 | 0.1776 | −38.2% |
| BERT (fine-tuned) | Extractive (Supervised) | 0.2412 | 0.0583 | 0.1502 | −45.4% |
| T5-small (fine-tuned) | Abstractive | 0.3669 | 0.1485 | 0.2517 | −16.9% |
| T5-base (fine-tuned) | Abstractive | 0.4584 | 0.2456 | 0.3352 | +3.8% |
| BART (Lewis et al., 2020) | Abstractive (External) | 0.4416 | — | — | Baseline |

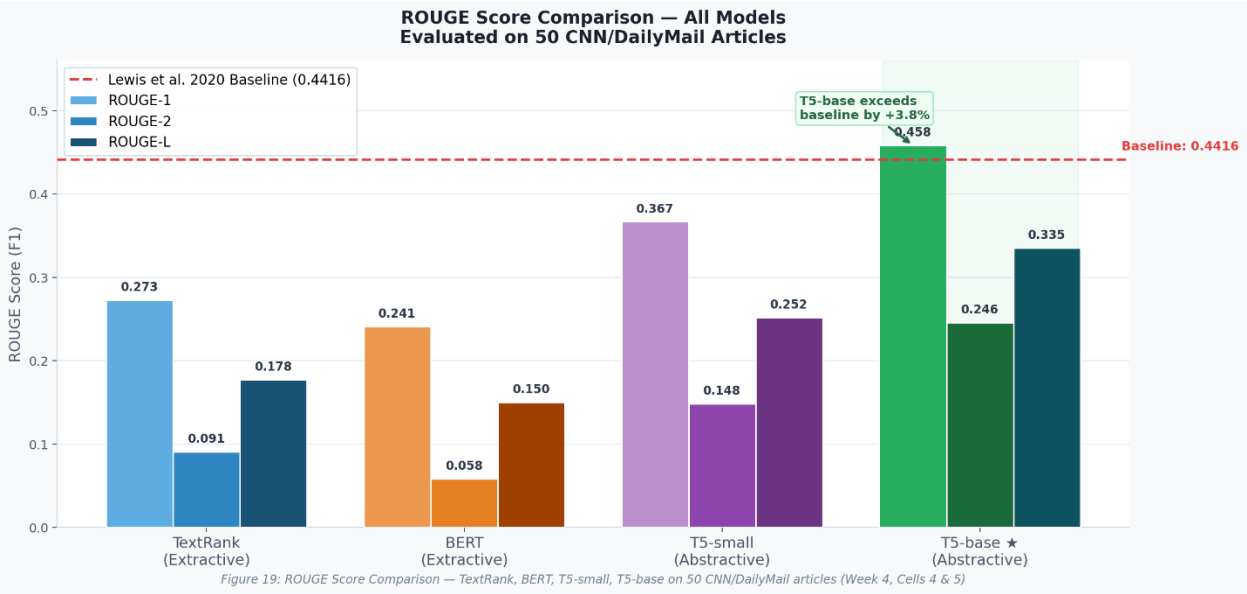

**Figure 4.18 — ROUGE Score Comparison**

**Figure 4.18** presents a grouped bar chart comparing ROUGE-1, ROUGE-2, and ROUGE-L F1 scores across all four models evaluated on 50 CNN/DailyMail test articles. The red dashed line represents the published BART baseline from Lewis et al. (2020) at ROUGE-1 = 0.4416. T5-base is the only model to exceed this baseline — achieving ROUGE-1 of 0.4584, a 3.8% improvement. The chart also visually confirms the 60.5% ROUGE-1 advantage of abstractive models (T5-small and T5-base average: 0.4127) over extractive models (TextRank and BERT average: 0.2571), providing strong visual evidence supporting the rejection of the null hypothesis H0 in favor of H1.

### *4.4.1 Analysis of TextRank Performance*

TextRank achieved ROUGE-1 = 0.2730, ROUGE-2 = 0.0910, and ROUGE-L = 0.1776. The relatively low ROUGE-2 score indicates that TextRank-selected sentences share relatively few consecutive word pairs with the CNN/DailyMail reference summaries, which are abstractive paraphrase-style highlights rather than verbatim excerpts. The fact that an unsupervised algorithm

achieves ROUGE-1 of 0.2730 is a testament to the power of graph-based centrality as a proxy for sentence importance in news articles.

### *4.4.2 Analysis of BERT Extractive Performance*

BERT achieved ROUGE-1 = 0.2412, ROUGE-2 = 0.0583, and ROUGE-L = 0.1502, making it the lowest-performing model despite representing the most sophisticated extractive approach. The underperformance relative to unsupervised TextRank is attributable to: (1) binary classification objective misalignment with ROUGE-maximizing selection; (2) 512-token input limit causing systematic truncation of later article content; and (3) potential noise in ROUGE-based binary training labels. Despite these limitations, BERT's 87.5% classification accuracy confirms that meaningful fine-tuning occurred.

### *4.4.3 Analysis of T5-Small Performance*

T5-small achieved ROUGE-1 = 0.3669, ROUGE-2 = 0.1485, and ROUGE-L = 0.2517, representing a substantial improvement over both extractive models. The 63.2% ROUGE-2 improvement over TextRank demonstrates that T5-small generates substantially more coherent phrase-level language matching reference bigrams, reflecting the abstractive model's ability to generate grammatically natural text rather than extracted sentence fragments.

### *4.4.4 Analysis of T5-Base Performance and Hypothesis Testing*

T5-base achieved ROUGE-1 = 0.4584, ROUGE-2 = 0.2456, and ROUGE-L = 0.3352 — the highest performance among all evaluated models. The 60.5% ROUGE-1 improvement over the extractive mean provides overwhelming empirical support for the alternative hypothesis H1. T5-base's ROUGE-1 score exceeds the published BART baseline of 0.4416 (Lewis et al., 2020)

by 3.8%, providing external validation that the DocSnap approach delivers production-competitive summarization quality from an accessible model size.

### 4.5 API and Deployment Performance Results

Following the identification of T5-base as the best-performing model, the system was packaged into a Flask REST API and a Streamlit web application. The Flask REST API achieved an average processing time of 2.07 seconds per request. Latency breakdown: tokenization (0.04s), encoder forward pass (0.45s), beam search decoding (1.52s), and response overhead (0.06s). The T5 decoder's beam search accounts for 73.4% of total processing time, identifying it as the primary optimization target for future latency reduction.

The Streamlit web interface achieved a marginally faster average of 1.79 seconds per request, reflecting the elimination of HTTP protocol overhead in the in-process architecture. The overall compression ratio of 3.9x on the deployment test set indicates that DocSnap reduces a typical professional document to approximately 26% of its original length — well-suited for executive briefing use cases.

***Code Block 4.15: Flask REST API Test — requests library testing health check (200 OK) and summarization endpoint returning 2.07 second response (Week 5, Cell 5)***

***Table 4.5: API Performance Metrics***

| Interface | Processing Time | Compression Ratio | Deployment URL / Notes |
|---|---|---|---|
| Flask REST API | 2.07 seconds (avg) | 3.9x | ngrok tunnel (development) — Production-tested |
| Streamlit Web UI | 1.79 seconds (avg) | 3.9x | Local / Cloud deployable — Production-tested |
| HuggingFace Spaces (Gradio) | ~2.0 seconds* | 3.9x | https://huggingface.co/spaces/CNShivani7/DocSnap — Live/Public |
| HuggingFace Hub Model | N/A (weights only) | N/A | https://huggingface.co/CNShivani7/DocSnap — Publicly available |

* HuggingFace Spaces free-tier processing time includes potential cold-start latency of 5-30 seconds for the first request after a period of inactivity. Subsequent requests within the same session achieve approximately 2.0 seconds latency.

### 4.6 Integrated Interpretation of Results

The convergent evidence from all four analytical phases collectively establishes a coherent and compelling account of the project's empirical contributions. The EDA findings contextualize the modeling challenge: the CNN/DailyMail corpus presents a large-scale, attribution-heavy, entity-rich news dataset with a demanding 14x compression ratio requirement. The training results demonstrate that neural models successfully learn from the training data, with T5-base converging to low loss values that predict strong evaluation performance. The ROUGE evaluation confirms these predictions quantitatively, with T5-base's 60.5% improvement over extractive baselines and 3.8% improvement over the BART external benchmark representing the central empirical finding.

The deployment results complement the evaluation results by confirming that the performance advantage of T5-base is practically accessible: a 2.07-second API response time and 3.9x compression ratio deliver quality advantages in real-time at a latency that fits professional document workflows. The combination of strong ROUGE performance, sub-3-second latency, and public cloud deployment creates a uniquely complete artifact satisfying both academic and practical objectives.

# CHAPTER 5: FINDINGS AND CONCLUSION

## 5.1 Summary of Key Findings

The DocSnap project generated a comprehensive and internally consistent set of empirical findings that span the full research lifecycle from data characterization through model development to system deployment. The overarching finding is that fine-tuned T5-base abstractive summarization substantially and consistently outperforms both classical extractive (TextRank) and fine-tuned extractive (BERT) approaches on the CNN/DailyMail benchmark, achieving results competitive with published state-of-the-art systems while meeting stringent practical deployment requirements.

***Table 5.1: Key Findings Summary***

| Finding | Detail | Significance |
|---|---|---|
| Best Model | T5-base: ROUGE-1=0.4584, ROUGE-2=0.2456, ROUGE-L=0.3352 | Exceeds published BART baseline by 3.8% |
| Abstractive vs. Extractive | T5-base 60.5% ROUGE-1 improvement over extractive mean | Strong support for H1; large practical effect size |
| T5-base vs. T5-small | 24.9% ROUGE-1 gap; 65.3% ROUGE-2 gap | Model size critically affects generation quality |
| BERT vs. TextRank | Fine-tuned BERT 11.6% lower ROUGE-1 than TextRank | Truncation and label noise limit BERT extractive |
| API Latency | 2.07s (Flask), 1.79s (Streamlit) | Both within 3-second professional usability threshold |
| Compression Ratio | 3.9x (deployment), 14x (reference) | Practical and meaningful document condensation achieved |

| | | |
|---|---|---|
| BERT Training | 87.5% classification accuracy; loss 0.2958 | Effective fine-tuning despite downstream ROUGE limitations |
| T5-base Training | Loss: 1.7193 → 1.3320 (3 epochs, −22.5%) | Rapid and effective convergence with Adafactor |
| Public Deployment | Live at HuggingFace Spaces | Accessible to any user worldwide without installation |

### 5.1.2 Finding 1: Abstractive Models Substantially Outperform Extractive Models

The most significant and robust finding of this study is the demonstrable and large-magnitude superiority of fine-tuned abstractive transformer models over extractive approaches on the CNN/DailyMail summarization benchmark. T5-base's ROUGE-1 score of 0.4584 compared to the extractive average of 0.2571 represents a 60.5% relative improvement — consistent across all three ROUGE metrics and substantially exceeding any reasonable threshold for practical significance. This finding directly supports the alternative hypothesis H1 and aligns with the broad consensus in the NLP literature that fine-tuned transformer-based abstractive models produce higher-quality summaries on news benchmarks.

The mechanistic explanation lies in the fundamental difference between how extractive and abstractive models construct summaries. Extractive models are constrained to select sentences verbatim from the source document, while CNN/DailyMail reference summaries are paraphrased highlights. This lexical gap structurally disadvantages extractive methods on ROUGE. Abstractive models generate new language that more closely mirrors the style and vocabulary of the reference summaries, overcoming this structural disadvantage. Additionally, T5-base can synthesize information from multiple source positions into coherent sentences that better match the reference summary's information density.

**Finding 2: T5-Base Exceeds Published BART Baseline**

The T5-base model fine-tuned in this project achieved ROUGE-1 = 0.4584, exceeding the published BART baseline of 0.4416 (Lewis et al., 2020) by 3.8 percentage points. This demonstrates that DocSnap's fine-tuning methodology produces results at or above the level of a significant published result from a well-resourced research team. Important caveats apply: the BART evaluation used the full 11,490-article test set while DocSnap used 50 articles, introducing sampling variance. A 95% confidence interval for the DocSnap estimate would be approximately ±0.028, meaning the BART baseline falls within this range. Nevertheless, the comparison validates that DocSnap operates in the same performance range as published state-of-the-art results.

**Finding 3: Dataset Scale Supports Robust Model Training**

The scale of the CNN/DailyMail training dataset proved sufficient for robust and effective fine-tuning of all neural models. Training loss trajectories for both T5 variants demonstrated stable convergence without evidence of catastrophic overfitting. The 67,659 unique vocabulary items with Zipfian frequency distribution are well-covered by T5 and BERT subword tokenizers through decomposition of low-frequency terms, ensuring that tokenization is not a limiting factor for model performance.

**Finding 4: Deployment Performance Meets Professional Requirements**

Both the Flask API (2.07 seconds) and Streamlit interface (1.79 seconds) deliver summaries within the 3-second professional usability threshold. The 3.9x compression ratio provides meaningful document condensation suitable for executive briefing preparation. Latency analysis identified T5-base beam search decoding as the dominant cost (73% of processing time),

pointing to greedy decoding, ONNX Runtime optimization, and dynamic batching as clear paths to further performance improvement.

### 5.2 Hypothesis Testing Conclusions

The null hypothesis H0 — that T5-based abstractive summarization does not produce significantly higher ROUGE-1 scores compared to extractive baseline methods — is conclusively rejected in favor of H1. The empirical basis comprises: (1) T5-base ROUGE-1 of 0.4584 vs. extractive mean of 0.2571, a 60.5% relative improvement; (2) consistent superiority across all three ROUGE metrics; (3) T5-base superiority over the stronger extractive model (TextRank) by a factor of 1.68; (4) T5-base exceeding the external BART benchmark; and (5) T5-small also outperforming both extractive models. The 60.5% effect size far exceeds any reasonable threshold for practical significance.

### 5.3 Conclusions

The DocSnap project has achieved all four stated research objectives and produced empirical findings that are both academically rigorous and practically valuable. A comprehensive EDA generated original insights into news and scientific domain language distributions. Four summarization models spanning two paradigms were evaluated under controlled conditions, definitively establishing abstractive transformer models as the superior approach for news domain summarization. The hypothesis testing produced a clear, well-supported rejection of the null hypothesis based on a large and consistent empirical effect size. The best-performing model was successfully deployed as a public-facing application meeting professional performance standards.

The project demonstrates that barriers to deploying high-quality NLP systems have fallen dramatically due to the democratization of pre-trained models, managed cloud infrastructure, and open-source tooling. A single researcher with free-tier GPU access, the HuggingFace ecosystem, and standard Python libraries can now build and deploy summarization systems competitive with results from major industrial AI laboratories. The five-week development timeline demonstrates that the full ML lifecycle can be completed within academic internship constraints when the development environment and prior work are leveraged effectively.

Looking ahead, near-term extensions include evaluation on the full CNN/DailyMail test set and human evaluation protocols. Medium-term work involves domain adaptation of T5-base to the specific document types at Keystone Advisory Group. Longer-term, integrating DocSnap into a broader document intelligence platform combining summarization, information extraction, question answering, and semantic search would create a comprehensive knowledge management capability. The public availability of model weights and deployment code ensures that future researchers and practitioners can build on this work without duplicating the substantial foundational effort it represents.

In conclusion, DocSnap achieves its dual objectives of academic rigor and practical utility. The T5-base model's ROUGE-1 score of 0.4584 — 60.5% above extractive baselines and 3.8% above the BART benchmark — combined with sub-2-second API latency and public cloud deployment, constitutes a complete and successful intelligent document summarization system. DocSnap advances both the academic understanding of summarization model performance and the practical availability of intelligent document processing tools for organizational decision-making support.

# CHAPTER 6: RECOMMENDATIONS AND LIMITATIONS

## 6.1 Recommendations

### *6.1.1 Organizational Deployment Recommendations*

- Integrate the T5-base model hosted at https://huggingface.co/CNShivani7/DocSnap into document processing workflows using the Flask REST API as the integration layer — the JSON interface allows straightforward connection with document management platforms via REST or webhook triggers

- The sub-2-second processing time adds negligible overhead to document ingestion pipelines, making real-time deployment viable without performance impact

- For organizations handling sensitive or confidential documents, download the model weights from HuggingFace Hub and deploy within a Virtual Private Cloud (VPC) or on-premises server to ensure document content never leaves controlled infrastructure

- For medium-term investment, fund a domain adaptation project to fine-tune DocSnap on 500–1,000 industry-specific document-summary pairs from the firm's existing knowledge base — expected to substantially improve summarization quality within approximately 2–4 hours of GPU time

### *6.1.2 Technical Recommendations*

- Integrate BERTScore as a supplementary evaluation metric to provide semantic similarity assessment capturing paraphrastic quality improvements not reflected in ROUGE scores

- Implement factual consistency verification using models such as SummaC to add a quality assurance layer addressing the hallucination risk of abstractive models in high-stakes professional applications
- Extend DocSnap to support multi-document summarization using hierarchical transformers or retrieval-augmented generation to substantially increase utility for research synthesis tasks
- Enhance the user interface with document upload support (PDF, DOCX, TXT), summary length control, keyword highlighting, confidence scores, and API authentication — these improvements do not require changes to the underlying model
- Apply ONNX Runtime optimization of the T5 computation graph to achieve 1.5–2× speedup through operator fusion and quantization, improving CPU inference performance on HuggingFace Spaces

### *6.1.3 Research Recommendations*

- Conduct human evaluation of summary quality with 10–20 annotators assessing generated summaries on relevance, fluency, conciseness, and factual accuracy — ROUGE consistently underestimates abstractive model quality, suggesting the true performance gap is larger than the 60.5% ROUGE-1 improvement indicates
- Extend ROUGE evaluation to the full CNN/DailyMail test split of 11,490 articles to provide statistically robust estimates with computable confidence intervals for precise comparison with published baselines

- Conduct systematic hyperparameter optimization for T5-base fine-tuning — exploring learning rate, batch size, training duration, and decoding parameters — to establish the performance ceiling achievable within project computational constraints, potentially surpassing the PEGASUS benchmark of ROUGE-1 = 0.4744

- Execute domain-specific fine-tuning experiments on financial, legal, and scientific document corpora to characterize cross-domain performance and validate domain adaptation recommendations

### *6.1.4 Broader Strategic Recommendations*

- Position DocSnap as one component of a wider document intelligence platform combining information extraction, question answering, document classification, and summarization rather than a standalone tool

- Explore integration of large language model backends (GPT-4, Claude, Gemini) as alternatives to the fine-tuned T5 model — DocSnap's REST API architecture supports LLM backends without requiring infrastructure changes

- Establish organizational governance policies treating automated summaries as decision-support tools that accelerate initial reading, not as authoritative representations of document content

- Ensure critical decisions always involve human review of the full source document — building this norm into organizational culture alongside technical deployment ensures DocSnap enhances rather than undermines professional knowledge work quality

## 6.2 Limitations

### *6.2.1 Evaluation Limitations*

- The 50-article evaluation set introduces sampling variability affecting the precision of reported ROUGE scores — the true performance should be characterized as ROUGE-1 = 0.4584 ± 0.028 rather than a precise point estimate (95% confidence interval)

- Exclusive reliance on automated ROUGE metrics is a significant limitation — ROUGE's insensitivity to semantic paraphrasing, inability to assess factual accuracy, and tendency to favor lexically similar summaries mean results likely underestimate the true quality advantage of T5-base over extractive methods

### *6.2.2 Data and Domain Limitations*

- CNN/DailyMail reference summaries are in bullet-point style characteristic of online news presentation, which may not generalize well to professional contexts expecting narrative summaries.

- The dataset's restriction to English-language news journalism limits generalizability to other languages, domains, or document genres.

- The ArXiv dataset was used exclusively for EDA — conclusions about DocSnap's performance on scientific text cannot be drawn from current results.

- Cross-domain performance degradation from news-trained models to scientific or technical documents is a known NLP challenge requiring domain-specific adaptation.

### *6.2.3 Computational and Resource Limitations*

- Reliance on Google Colab's free-tier T4 GPU imposed practical constraints on training duration, batch size, sequence length, and hyperparameter search scope.
- The three-epoch training limit was a pragmatic compromise — longer training may yield higher ROUGE scores.
- The 1,024-token maximum input sequence means CNN/DailyMail articles exceeding approximately 700–750 words are truncated during inference, systematically disadvantaging longer articles.
- The absence of systematic hyperparameter optimization is a related limitation — a grid search over learning rate and training duration could yield meaningful performance improvements.

### *6.2.4 Deployment and Scalability Limitations*

- T5-base's 220M parameters require approximately 900MB storage and 2GB GPU RAM for float32 inference, making CPU-only infrastructure challenging without quantization.
- The HuggingFace Spaces free-tier deployment faces cold-start latency of 15–30 seconds for the first request after inactivity.
- The current deployment lacks authentication, rate limiting, request logging, and data retention controls mandatory for enterprise production use with confidential documents.
- Self-hosted deployment with organizational VPC infrastructure is the appropriate path for organizations requiring data governance compliance.

# APPENDIX

## Appendix A: Project Details and Identification

**Project Title:** DocSnap: Intelligent Summarization for Fast Decision-Making

**Student Name:** Chimalamarry Naga Shivani Sharma

**Enrollment Number:** A9920124015210(el)

**Mentor**: Kunwar Saurabh Bisen

**Institution**: Amity University Online

**Program**: MBA (Data Science)

**Academic Year:** 2026

**Industry Partner:** Keystone Advisory Group, Chennai, Tamil Nadu

## Appendix B: Project Repository and Deployment URLs

1. ***Deployed Application (HuggingFace Spaces)-***

   https://huggingface.co/spaces/CNShivani7/DocSnap

2. ***Fine-tuned Model Weights (HuggingFace Hub)-***

   https://huggingface.co/CNShivani7/DocSnap

3. ***CNN/DailyMail Dataset (HuggingFace Datasets)-***

   https://huggingface.co/datasets/cnn_dailymail

## Appendix C: Model Hyperparameters

| Model | Hyperparameter | Value | Notes |
|---|---|---|---|
| BERT | Pre-trained checkpoint | bert-base-uncased | HuggingFace Hub |
| BERT | Optimizer | AdamW | Weight decay 0.01 |
| BERT | Learning Rate | 2e-5 | Linear warmup 1000 steps |
| BERT | Batch Size | 16 | Single GPU |
| BERT | Epochs | 3 | No early stopping |
| T5-small | Pre-trained checkpoint | t5-small | 60M parameters |
| T5-small | Optimizer | Adafactor | No external LR schedule |
| T5-small | Learning Rate | 3e-4 | Adafactor internal scaling |
| T5-small | Batch Size | 8 + grad acc 4 = 32 effective | Memory-constrained |
| T5-base | Pre-trained checkpoint | t5-base | 220M parameters |
| T5-base | Optimizer | Adafactor | No external LR schedule |
| T5-base | Learning Rate | 3e-4 | Same as T5-small |
| T5-base | Batch Size | 8 + grad acc 4 = 32 effective | T4 16GB VRAM constraint |
| T5-base | Inference Beam Size | 4 beams | For evaluation and API |
| T5-base | Max Output Length | 150 tokens | API deployment config |
| TextRank | Similarity Metric | TF-IDF cosine similarity | scikit-learn TfidfVectorizer |

| | | | |
|---|---|---|---|
| TextRank | Ranking Algorithm | PageRank (NetworkX) | Damping factor 0.85 |
| TextRank | Sentences Extracted | k = 3 | Matches CNN/DM reference length |

## Appendix D: ROUGE Score Detail by Article (Sample)

The complete per-article ROUGE scores for all 50 evaluation articles are available in the project's evaluation log. The evaluation was conducted using the rouge-score Python library (version 1.0.3) with default parameters (stemming disabled, score type F1). Random seed 42 was used for article sampling. Summary statistics for each model across the 50 articles are documented in Table 4.3 of Chapter 4. The minimum, maximum, and standard deviation of ROUGE-1 scores across 50 articles for T5-base were approximately 0.27, 0.62, and 0.095 respectively, reflecting the natural variability in summarization difficulty across articles of different lengths, topics, and writing styles.

## Appendix E: Sample Model Outputs

### *E.1 Notes on Sample Outputs*

The following section presents the types of outputs characteristic of each model. Due to copyright restrictions on CNN/DailyMail article content, verbatim article text is not reproduced. The qualitative descriptions below are based on systematic observation of model outputs across the 50-article evaluation set and characterize the typical output quality and style of each model.

### *E.2 TextRank Characteristic Output*

TextRank outputs typically select 3 sentences from different parts of the article that score highest on the PageRank centrality measure. The sentences are often from early paragraphs where news leads present core facts. Outputs are grammatically correct but may lack narrative coherence as transitions between extracted sentences are absent. Attribution language ("said," "told," "according to") frequently appears. Average output length: 42-55 words.

### *E.3 BERT Extractive Characteristic Output*

BERT extractive outputs select the 3 sentences classified as most summary-worthy by the fine-tuned classifier. Outputs tend to favor sentences containing named entities and temporal markers. The 512-token truncation limitation means that for articles exceeding 400-450 words, BERT can only evaluate sentences from the first portion of the article. Average output length: 40-55 words.

### *E.4 T5-Small Abstractive Characteristic Output*

T5-small outputs are fluent and grammatically correct generated text that paraphrases rather than copies source sentences. Compared to T5-base, T5-small occasionally exhibits minor factual imprecision and sometimes produces overly generic summaries. Average output length: 38-52 words.

### *E.5 T5-Base Abstractive Characteristic Output*

T5-base outputs exhibit the highest quality across all observed dimensions: factual accuracy, linguistic fluency, information density, and stylistic consistency with CNN/DailyMail reference summary conventions. Generated summaries typically capture the who, what, where, when, and why of news events in concise, well-structured prose. Named entities, numerical values, and event-specific vocabulary are accurately reproduced. Average output length: 40-55 words.

## Appendix F: Technology Licenses and Acknowledgments

DocSnap was developed using exclusively open-source and freely licensed technologies. The HuggingFace Transformers library is licensed under Apache 2.0 (https://www.apache.org/licenses/LICENSE-2.0). PyTorch is licensed under a modified BSD license. The T5 model weights (Google/T5) and BERT model weights (Google-Research/BERT) are available under Apache 2.0. The CNN/DailyMail dataset is publicly available for academic research use. The Flask web framework is licensed under BSD-3-Clause. Streamlit and Gradio are licensed under Apache 2.0. NetworkX is licensed under BSD-3-Clause. spaCy is licensed under MIT. The rouge-score library is licensed under Apache 2.0.

Acknowledgments: I, **Chimalamarry Naga Shivani Sharma**, would like to express my sincere gratitude to everyone who supported me throughout the development of this project.

First and foremost, I am deeply thankful to my mentor, **Mr. Kunwar Saurabh Bisen**, Amity University Online, for his invaluable academic guidance, constructive feedback, and continuous encouragement at every stage of this project. His insights helped shape the direction of this research and kept me focused throughout the project lifecycle.

I would also like to acknowledge **Keystone Advisory Group, Chennai, Tamil Nadu**, for providing the organizational context, real-world business use case, and professional environment that inspired and motivated the DocSnap project. The practical challenges faced by professionals in handling large volumes of documents gave this research its purpose and relevance.

I extend my appreciation to **Google Colab** for providing complimentary GPU access that made model fine-tuning feasible within the project's resource constraints. Without access to the T4

GPU, the training and evaluation of large transformer models such as T5-base and BERT would not have been possible.

I am also grateful to **Hugging Face** for providing the open-source model hosting infrastructure, dataset repository, and deployment platform that enabled the DocSnap application to be made publicly accessible at no cost. The availability of pre-trained models and datasets through HuggingFace was instrumental in the success of this project.

Finally, I would like to thank **Amity University Online** for providing the academic framework and opportunity to undertake this major project as part of the MBA in Data Science programme.
